Praise for *The Rife Handbook*

Natural therapies and healing have been ridiculed as quackery by the medical-pharmaceutical complex for a century. Yet consumers spend thirty billion out-of-pocket dollars a year on alternative therapies. Why? Not because people are gullible, but because many of these modalities work. Holistic health is complex. It addresses the entire body, all one hundred trillion cells. Supported by abundant research, Nenah Sylver does an amazing job explaining the plethora of options, techniques and technologies that will help readers make informed decisions about how to naturally support their health and innate healing power. Simply put, *The Rife Handbook* is an encyclopedia of holistic health. It's so comprehensive, it's mind boggling. This stellar body of work belongs in every household as well as every practitioner's office.

—Bernard Straile, DC
author of *One Thousand Shades of Pink*
and developer of the IMAET quantum energy wellness equipment

This book is incredibly well written and comprehensive, relevant to students and practitioners alike. Covering an array of topics in medicine and holistic health, it comes at a most crucial time in the burgeoning field of alternative and complementary health care. Having read scores of books on electromedicine, I count this book as my number one reference on the topic. I only wish I had the knowledge presented in these pages many years ago. As a scientist with over forty years of clinical and academic experience, I am mesmerized by Nenah Sylver's quality of writing and knowledge. She explains the most difficult topics clearly so anyone can understand and benefit from what she has to offer. Dr. Sylver is sure to inspire and educate those fortunate enough to hold a copy of her book in their hands. Without question, she will be included as one of the great minds of the 21st century. It is with great pride and honor that I recommend *The Rife Handbook* without hesitation to all physicians and students in the health field.

—John A. Amaro, PhD, DC, LAc, Dipl Med Ac
past president, International Academy of Medical Acupuncture
and developer, Electro Meridian Imaging (EMI)[™] acupuncture diagnostic instrument

In this 5th edition of *The Rife Handbook of Frequency Therapy and Holistic Health*—the definitive work on Rife, resonant frequency, pulsed energies, and related technologies for therapeutic use—Nenah Sylver has set an even higher bar of excellence. She has conveyed so much new and important information in an even more organized and cohesive manner, that this edition is a “must have” even if you enjoyed the previous volume.

Dr. Sylver's unique ability to translate complex information into accessible content, suitable for health professionals and laypersons alike, leave most hard-core technical persons (like myself) in total awe. Her attention to accurate historical detail as opposed to myth, and inclusion of new, cutting-edge complementary healing modalities, allows readers to strategize a practical and effective approach for their often serious health issues. This latest edition empowers the reader by providing a wealth of knowledge compiled, sorted, and refined over the last decade. It offers information that few have time to research for themselves when their health requires it the most. This book is an incredibly valuable resource that everyone needs. If you have but a single reference in your library on the science and practice of these technologies and therapies, *The Rife Handbook* should definitely be the one!

—Jimmie Holman
co-founder, Pulsed Technologies Research (USA)
and Bioenergetics & Pulsed Technologies (EU)

Traditional medicine, with its faulty paradigm and obsolete Neanderthal protocols, is already in a state of decline. In its wake, Integrative Medicine has begun to fill the void with bio-mechanical therapies, electromedicine, and more natural remedies to heal. Keeping up with the many advances is a monumental task.

The previous edition was a first-rate, comprehensive, extremely well organized and documented manual to help laypersons and physicians better understand the concepts of vibrational medicine and the power of complementary health protocols. As an author, researcher and international lecturer with over forty years of clinical experience, I was literally blown away by that masterpiece and gave it a definitive five-star rating. This revised 5th edition of *The Rife Handbook of Frequency Therapy and Holistic Health* is a perfect example of intelligent evolution. Dr. Nenah Sylver has compiled an even more comprehensive holistic bible. In an improved format, it provides frequencies to treat new diseases, plus expanded sections on the politics of medicine and vaccines, more breakthrough complementary therapies, historical electromedicine references, and other topics to help one survive the pitfalls of modern medicine. It's a must for everyone's reference library.

—Gerald H. Smith, DDS, DNM
past president, Holistic Dental Association

Dr. Nenah Sylver has brought together the sciences of bioelectronics and naturopathic health care in a truly integrated approach. *The Rife Handbook* is the bible of holistic medicine for the 21st century.

—Brian McInturff
creator of the Consolidated Annotated Frequency List (CAFL),
www.electroherbalism.com

Dr. Nenah Sylver has gifted humanity with a magnificent, comprehensive, thoroughly researched guide to holistic health as well as the science and application of the work of a great medical pioneer, Royal Raymond Rife. This book will help physicians expand their base of practical and theoretical knowledge. I highly recommend it for any clinical practice utilizing complementary and energy medicine therapies.

—Robert S. Ivker, DO
co-founder and past president, American Board of Integrative Holistic Medicine (ABIHM)
and author of Sinus Survival

At a time when health conscious individuals are concerned about drug-resistant infectious diseases, the government's push for mass inoculations, the over-medication of children, bioterrorism, and negative effects of vaccines and drugs, along comes a well researched, easy-to-read treatise that revives non-invasive and effective frequency therapy. *The Rife Handbook* is sophisticated enough for the seasoned health professional, yet thorough and understandable enough for the novice. This book does more than discuss the genius of Royal Raymond Rife; it superbly explains holistic approaches to treating disease. Even if the reader does not (yet) own a frequency device, this book is one of the best primers I have ever seen on holistic health. Anyone interested in alternative healing protocols must have this book.

—Rose Marie Williams, MA
Townsend Letter columnist, and natural health and environmental advocate

This 5th edition of *The Rife Handbook* is huge. Our definition of “handbook” must expand to include the book’s thousand-odd pages—making it a little unwieldy in the field, but absolutely worth keeping at the desk. It’s enormous in scope, but Nenah Sylver eases us into the text by explaining, in the Introduction, the premise under which she operates: “It became clear to me that I couldn’t just create a list of numbers [frequency settings] to go with the equipment . . . it wasn’t enough to receive frequency sessions; [people] had to actively eliminate the conditions that had allowed their illness to occur in the first place.” The end result is truly a comprehensive volume of healing.

Healing invariably makes us think of germs. But as Dr. Sylver writes, “As long as we perceive ourselves as helpless victims of germs, we’ll continue to rely on pharmaceuticals to help us get well.” A famous senior executive at GlaxoSmithKline (whom she quotes) once publicly admitted that over 90% of pharmaceuticals are only about 30%–50% effective (depending on the genetics of the person to whom they are administered). Dr. Sylver discusses the effectiveness and toxic effects of pharmaceuticals in depth. The political aspect of both pharmaceutical drugs and their marketing is also discussed and referenced extensively. The section on vaccination is to be particularly noted—the history, politics, science, and their incorporation into our own genetic material (a sort of biologic gene editing phenomenon). And that is only Chapter 1.

Other highlights made a particular impression as well. Dr. Sylver discusses the inventions of Royal Rife and the discoveries of other healers in this field of holistic medicine. The entire history, as recounted in this book, is sordid, and reflects very poorly on the medical establishment, including the American Medical Association. We are given a multitude of choices for healthy living—with the caveat that “one size fits all” does not work for either bathrobes or diets. I was especially drawn to the section on gratitude, toward both the animals and plants that provide us with our food. The Brix measurement of plant vitality was a brand new one to me. High Brix means more nourishment, and is measured by placing a drop of plant juice on a device called a refractometer and seeing how much the light is bent as it passes through the prism. There is also a very interesting discussion of wheat, and how it has become modified from the original 14-chromosome gluten-poor grain to the current 42-chromosome gluten-rich grain associated with multiple forms of illness known as “gluten intolerance.”

One of the appendices gives an excellent discussion of various electromagnetic frequency devices and magnetic therapy in general. Another appendix satisfies the research junkies among us, a list of published papers and books on electromedicine dating back to 1877. Plus, there are still all the chapter references, almost five hundred for Chapter 1 alone. Appendix E gives a tantalizing glimpse of current research on frequency treatment of cancer cells *in vitro*. And Appendix F lists commonly used chemicals, almost all of which are toxic to human life. There is so much more to this book that you need to read it for yourself and decide what your favorite portions are.

If you want to learn about Rife therapy or the context in which it is best used, this book is an excellent place to start. It is also an invaluable reference manual for complementary therapies and holistic living in general. The writing is superb. The information is well researched, logically presented, and accurate. “We cannot die in peace without living in love,” writes Nenah Sylver. The overall impression this book leaves is one of light and healing.

I am beyond impressed.

Royal Rife developed equipment to apply frequencies. Since that time, various types of effective frequency devices have been produced. Hundreds of cancer patients have recovered without the benefit of surgery, chemotherapy, or radiation. Lyme disease, Multiple Sclerosis, rheumatoid arthritis, and many other conditions have yielded to frequency therapies. Non-professionals have produced many of these results. I have had the privilege of watching many people self-treat and enjoy improvements in their health.

An attorney with an autistic son reported that her child seldom slept more than three hours at a time; he would wake up in pain. The two of them were getting six hours or less of sleep a night. After the mother gave the boy one frequency session, he started sleeping consistently for ten hours, and his behavior improved. A prostate cancer patient had difficulty urinating and tried frequency therapy. Five days later, the urine flow was normal. A leukemia patient had a white blood cell count of 250,000. He decided to use frequencies that other leukemia patients had found useful. After six weeks, his white blood cell count was down to 16,000. A patient with pulmonary fibrosis made crinkling sounds in his lungs as he breathed. He was told that his prognosis was hopeless, that his oxygen saturation would continue to decrease until not even inhaling oxygen would keep him alive. After frequency therapy he coughed up a lot of material, after which his lung sounds and oxygen saturation returned to normal. Several people with degenerative hip conditions have used frequency therapies. So far, all have recovered. It appears that when the infections in the joints are removed, the body is able to repair the damage. And yet, most physicians have never heard of Rife's work.

The Rife Handbook of Frequency Therapy is a book that doctors and their patients can use to learn about this safe, effective and non-toxic therapy for cancer and so many other conditions. Dr. Sylver presents a fascinating account of the life of Dr. Rife and his accomplishments. She describes how his discoveries were, and continue to be, ignored or opposed. She explains why you may not get the best available care when you seek medical help. She covers in detail helpful steps to take in moving toward wellness, including how to get quality water and how to detoxify the body. She covers what you need to know to conduct a frequency therapy session. She lists a large number of conditions with appropriate frequencies. And she offers a wide range of complementary therapies that are natural, effective, and easy to use for a wide variety of ailments. Dr. Sylver has spent years studying how people get sick and how they can get well. She presents a wealth of valuable material that will be beneficial to all kinds of practitioners including doctors, and to those on the road to recovering their own health.

Nenah Sylver's direct style is a prophetic voice for the medicine of the future. She provides a well-organized history of Rife's work and a seminal guidebook for the modern application of his discoveries. This significant volume will encourage lively and informed discussion regarding the implications of bio-electromagnetic energies for human wellness.

Dr. Nenah Sylver's 2001 edition offered an impressive collection of long-suppressed information to help people break away from the self-serving deceptions employed by conventional allopathic medical care and the pharmaceutical industry. With this new volume, Dr. Sylver demonstrates her mastery of this complicated field with massive amounts of hands-on information that you must learn if you are to finally be well. She courageously demonstrates how each of us has the power to take charge of our own lives and create our own wellness protocols, without abdicating responsibility to anyone else. *The Rife Handbook* is destined to become the definitive reference on attaining self-directed, holistic health.

—S. Nathan Berger, DDS, PC
Rife researcher and biological dentist

It doesn't happen very often, but occasionally I read a massive book on natural health and healing that just plain blows me away. Dr. Nenah Sylver's huge and impressive *Rife Handbook* is more than merely the best and most complete compendium on frequency healing that I've ever seen. In addition to a massive cross-referenced frequency directory for most human ailments, this wonderful book also features detailed, helpful, and groundbreaking information on complementary therapies—and much, much more.

—Chet Day
Health & Beyond Online, www.chetday.com

As an AAMA Board Certified Alternative Medicine Practitioner, I have many fine modalities from which to choose. I recently experienced a health issue that failed to be helped by either conventional allopathic medicine or even alternative medicine treatments. However, after a Rife frequency square wave treatment protocol was applied, this health issue was completely resolved.

Rife technology, until now, has been largely questioned by both alternative medicine and allopathic practitioners for efficacy and disease resolution. But *The Rife Handbook* will dispel your doubts. It is the recommended work for practitioners who need to understand how and why this therapy works, and who want to utilize frequency therapies in conjunction with current preferred interventions to help their patients heal. Nenah Sylver's definitive interpretation of frequency therapy identifies applications, indications, contraindications, safety, and specific treatments along with directions specifying "how, when, and what frequency" for therapy sessions. The detail with which the author examines treatment modalities is remarkable; she presents a variety of protocols to resolve most health issues. It is rare that I read another's views of various alternative medicine therapies that exude such succinct clarity and comprehension as hers. Dr. Sylver has a remarkable grasp of what works, how it works, and on whom it may be effective.

This well-referenced treatise provides treatment options when progress falls short, or when there appears to be an impassable plateau in the way of optimal recovery.

—Bill Misner, MS, PhD
AAMA Board Certified Alternative Medicine Practitioner

When Nenah Sylver published the first edition of *The Rife Handbook* in 2002, it received excellent reviews as the best book in the field. This new version is substantially updated and improved, reflecting many of the advances in frequency therapies that have occurred in over a decade. Frequency therapy, properly applied, may well replace every other modality. Frequencies can alter DNA, kill or enhance cells, affect all chemical interactions, break up toxic substances and cause them to be eliminated from the body, kill pathogens that disrupt bodily function, and enhance and stimulate all cells and organ systems to higher levels of performance.

There are superbugs and bioengineered diseases out there that might make it to your neighborhood. Will your local medical clinic help you when thousands of people are dying from a strange disease? Don't count on it! If you want to live long and prosper, learn about frequency therapy. Dr. Sylver spends a lot of time in her book to help you use frequencies safely. Even if you just want to make life a little better for your family and friends, you will want to read *The Rife Handbook*.

We work in the area of complementary and holistic cancer healing education and recommend Rife therapy to all our clients. *The Rife Handbook* is a bible in our office, an invaluable tool toward the healing of dozens of cancer victors. Nenah Sylver's research is thorough and detailed. The book sits on a prominent place on my shelf next to every frequently used manual in my practice.

Royal Raymond Rife discovered one of the most groundbreaking medical tools of the last hundred years. Due to political and financial interests, his discoveries were driven underground. But today, people suffering from cancer and other diseases can base their treatment on authentic science instead of politics. A scientist in the true definition of the word, Dr. Sylver methodically guides readers through Rife's life and achievements, with a history of the technology and the scientific foundation for its use. She also provides practical tips that can be easily integrated into a comprehensive protocol for a wide variety of health conditions. Nenah Sylver is the "researcher's researcher"; I habitually turn to her work as a trusted reference. I recommend *The Rife Handbook* without reservation to every health seeker, patient, physician, and scientist who values objectivity and innovation in medicine and wants guidance on complementary healing modalities.

The Rife Handbook of Frequency Therapy and Holistic Health: an integrated approach for cancer and other diseases.
Updated and Expanded 5th Edition

The first softcover edition of this book (with a different title) was published in 2001 by The Center for Frequency. Two larger, revised hardcover editions, almost identical, containing substantially new material, improved organization and an index, were published in 2009 and 2011 by Desert Gate Productions LLC. An updated and expanded 5th edition (with 1104 pages, almost 400 more pages than the 2011 volume) was published in 2018 by Desert Gate Productions LLC. In this second printing of *The Rife Handbook 5th Edition*, copyright 2021, a few errors have been corrected and some updates and newer material have been added to the text. The page count remains the same.

The information given in this *Handbook* is for educational, informational, and investigational purposes only. It is not to be construed as diagnosis of disease, treatment of disease, prevention of disease, or as a replacement for consulting a qualified medical practitioner.

Be careful when investigating this technology! Protocols may need to be modified, or used with only certain types of equipment and not others—or this technology may be contraindicated entirely—if you have a heart condition, are wearing a pacemaker or autodefibrillator, are pregnant, are nursing, have blood clots, are taking strong medications such as chemo, are taking herbal or nutritional supplements, have a medical need to suppress your immune function (such as organ transplant recipients who are taking immunosuppressive

drugs), are wearing metal implants or stents, have breast implants, are especially sensitive to radio frequency (RF) or other electromagnetic radiation, or have especially sluggish detox/eliminative functions (liver, colon, kidneys, and lymph system). Before using any equipment, and to see if you should even be experimenting with this technology, please read the beginning of Chapter 4, which explains these circumstances and the precautions to take. The author, publisher, distributors, and sellers of this book are not responsible or liable for the results of your experimentation with Rife Therapy or your use of any other protocols described in this book. The reader accepts full responsibility for any and all consequences of trying or using these modalities. *If you have a medical condition, see a qualified health professional of your choice.*

Acknowledgments

This book would never have been written without the pioneering discoveries and great personal sacrifices of Royal Raymond Rife. Likewise, I am indebted to the archivists, electronics engineers, microscopists, medical researchers, and others who came after Rife and continue to contribute to and refine the growing field of frequency therapies. This *Rife Handbook* is not intended to supplant anyone's research, discoveries, or devices. Rather, it is meant to guide you through Rife's healing modality that has reemerged and been updated, after being suppressed for over half a century. This book is also intended to provide you with a solid introduction to natural health so you can utilize this versatile frequency therapy to its best advantage.

Throughout the years, as this book has grown in size and detail, more people have critiqued it, adding to the complexity of its contents. There are many researchers in the Rife Therapy field who deserve to be acknowledged for their efforts to promote this drug-free, non-invasive modality, although not all are in the public eye (or want to be). Of those who can be named, I thank Brian McInturff for his early Consolidated Annotated Frequency List and continuing contributions to the Rife community; Jeff Sutherland, PhD, for his eclectic approach and assistance to me in the early years of this manuscript; and Jeff Garff, Shawn Montgomery, Jason Ringas, and Stanley Truman for allowing me to use documents and photos from their archives. I also thank Dave Felt, who spent many hours

patiently answering my questions and explaining technical issues (particularly as they pertained to engineering); and Marty Monahan, DC, NMD, who kindly gave me some additional frequencies he has used successfully in his clinical practice. Edna Tunney and her staff at Resonant Light Technology Inc. also have my thanks for giving me the kindest, most polite encouragement as only Canadians can. And I appreciate Bryan Rosner for his unique insights on protocols that help eliminate Lyme disease, as well as for his enthusiastic support.

There are some very special people in the forefront of the Rife community that I want to tell you about. Peter Walker, founder of the decades-old organization Rife Research, Europe and the Rife Forum (rifeforum.com)—and who then began hosting dozens of other types of health-related groups—has been instrumental in helping to keep the Rife community afloat and active, for which the world owes him a huge debt of gratitude. Over the years, Peter has graciously provided me with information and much practical assistance in many areas. I continue to be thankful for his dedication and efforts.

Another multitasking individual is Rife researcher, musician, mathematician, and historian Charlene Boehm. With her incisive mind for details and dedication to ethics and accuracy, Char would always make time to explain technical information. She also reviewed my history of Royal Rife and corrected a few errors—some of which had already been widely disseminated for years on the

Internet and on the printed page, and then unfortunately made their appearance in previous printings of this book.

Richard Loyd, PhD, is an exceptionally kind and caring researcher and practitioner. Dr. Loyd has generously shared his extensive knowledge of frequencies, his clinical findings, and many wonderful articles on electronics and nutrition. He has also freely and humbly acknowledged what has not worked, reminding me that sometimes, we learn from our mistakes even more than our successes.

Jimmie Holman of Pulsed Technologies is another person I have been honored to call a friend. Over the course of five editions of this book, this brilliant scientist has also functioned as a mentor. I will always treasure his willingness to share his innovative research, accompanied by a generous dose of patience as I sometimes struggled to understand what I was being taught.

Finally, I want to mention the late Steve Haltiwanger, MD, CCN. Steve possessed a giant intellect and encyclopedic knowledge, which he used in his many professional capacities to help countless health seekers. However, what I will equally remember him for is his kind and generous heart, which is what impelled him to so freely share what he knew with whoever wanted to learn. My many hours of discussion with Steve inspired me to include some important material in this book. Steve passed away after the 5th Edition was published but before this second printing was released. I will miss him.

On the practical side, some of the organizing assistance for past versions of Chapter 5, provided by Linda Thieman, MA, were retained for this current edition. Ann Rogers and Ron Strauss, who provided the index for earlier editions, laid the foundation for my indexing of this current volume. Duane Burchett, with good-natured patience, provided many versions of this new cover until I was satisfied.

Rife therapy should be administered holistically, as part of an overall wellness protocol. Therefore, this book addresses many complementary modalities. A project of this scope and depth could not have been completed without input from health professionals and educated laypersons versed in acupuncture, biology, chemistry, chiropractic, herbology, massage therapy, physics, and even law. There are too many people to name who provided input for both past and current editions. I trust that you all know who you are and will accept my thanks.

In the personal arena, I am blessed by two wonderful people who have become my family and constantly show me that our companions in life can help us work miracles and weather any storms, no matter how bleak life may appear. Throughout the decades that I labored on all

versions of this book, Paul Silverfox helped with countless everyday tasks so that I could spend uninterrupted hours writing. He reviewed all of the previous editions as well as this current one, remaining cheerful no matter how many rewrites I asked him to critique. From his perspective as a licensed massage therapist, he offered sage advice on many topics concerning health and gave me encouragement whenever I needed it. I will always treasure his friendship, support, wisdom, and common sense. For the 5th Edition and this second printing of the 5th Edition, James Dutcher provided enthusiastic and loving encouragement as well as highly personalized computer and software support. He upgraded, debugged, and repaired my computer—day or night, whenever it was needed. Most importantly, he spent many hours helping me navigate a frustrating and complicated software program for professional publishing. Doing my own manuscript layout was not only exhilarating and empowering, it immeasurably influenced my writing. I cannot emphasize enough how formatting this book myself allowed me to include more, essential, and timely information, organized in a way that makes complex data easier to absorb. In a sense, this book has been created for you by three people. I could never have written it without Paul and James. Having loving friends and comrades in life makes even gargantuan tasks manageable.

There are many others I want to acknowledge, even though I'll never meet them face-to-face. First are the thousands of people who, over the course of two decades, telephoned or emailed me about their health concerns. Their questions propelled me to search for answers, and because of that search I was able to write a better book. I also want to acknowledge members of the Internet health group community, people from all over the world who shared their very personal stories about how they were helped by frequency therapies and other complementary modalities. I found these accounts informative, inspiring, and often moving. Finally, I want to acknowledge those who sent me personal emails thanking me for writing this book and helping to make the quality of their lives better—and in some instances, for saving their lives. Whether or not I truly can (or should) accept credit for that feat, such comments literally take my breath away. When I receive such heartfelt missives, I know that I have succeeded in doing the job I'm supposed to be doing.

There is one more person I want to sincerely thank: you, the reader. Your courage to question the status quo, your desire to learn new ways of healing, and your willingness to take responsibility for your health, are a testimony to what holistic medicine is all about. It is in service to you that I have written *The Rife Handbook*.

Foreword by Steve Haltiwanger, MD, CCN

Medicine is a cult. Just as religion has its catechism, medicine has a set of credos based on faith. The faith says that if you take a pharmaceutical, it will fix everything. But this is a delusion. Pharmaceuticals do not heal. In order for true healing to take place, you need raw materials: amino acids, fatty acids, minerals, vitamins. Otherwise, cells do not work, tissue cannot be restored, and symptoms will not abate. They will not ever abate, not unless the body is given the chance to fix itself. Therefore it is my great pleasure and honor to be asked to write a foreword for this new edition of *The Rife Handbook*. It does not ask that you accept what is written on faith. You are presented with some solid science that organized medicine denies, the self-serving political agenda that organized medicine tries to cover up, and the contradictions in logic that organized medicine tries to pretend do not exist. And then it is up to you to decide what to do about your health.

I met Nenah Sylver at a scientific conference many years ago, and she and I stayed in constant contact thereafter. I found her to be a compassionate individual and a good friend. Nenah is not only an outstanding writer and the author of the best electromagnetic medicine book currently on the market, she is also a multi-talented musician and songwriter. A person of depth, she has lived an interesting life. She has always collected and surrounded herself with individuals who are curious and expansive in their vision. Not surprisingly, she gathers and assembles information the same way. She does extensive research, so her readers can be satisfied that

the information she has collated has been checked. She asks the same question, of several people, until she is satisfied with the answer. In her investigations into new developments in the scientific community, Nenah is in regular communication with innovators. This includes manufacturers of electromagnetic medicine equipment. Then she assembles a voluminous amount of information, and somehow it all neatly fits together into a book.

While this book has “Rife” in the title, it is a much broader review of multiple technologies that can be used to promote health. I ought to know. I have lectured for thirty-three years in seventeen countries on topics involving electromagnetic biology, infrared therapies, PEMF therapies, psychiatry, and nutritional treatments of neurological conditions. Over the last twenty-two years, I have participated in seventy-two research studies focused on the use of PEMF devices, microcurrent treatments, infrared therapies, photobiomodulation, nutritional supplementation, and laboratory analysis of human chemistry. I have formulated numerous nutritional supplements and I’m a consultant to several companies in the medical field. With my background and experience, I am pleased to say that this book is an invaluable contribution to the holistic and alternative medical fields. It is documented and sophisticated enough for the professional, and accessible enough for the layman.

With information expanding at a geometric pace, it is impossible to keep current with all the equipment that is being invented and produced. It is also difficult to keep

current with all the advances in complementary medicine. Therefore, although this is called a “handbook,” a better name might be “the bible of electromagnetic devices and complementary medicine made accessible to everyone.” My one complaint is that I don’t have enough time and money to buy and try all the technology described in this book.

This book is not the type that you usually read cover to cover. Instead, it is like an encyclopedia in which you search out specific topics that you have an interest in exploring. As you look through this book, you’ll discover how the properties of electricity, magnetism, light, and sound can be utilized by devices to affect and regenerate the human body. You’ll also learn about more complementary therapies than you possibly have time for. While these therapies reinforce the benefits of having an electromagnetic medical device, if you don’t own a piece of equipment just yet, the therapies can do a pretty good job on their own. In fact, the therapies are critical to becoming well and staying well.

Having had the pleasure of reading prior versions of this book, I am happy to report that this current version has vastly improved, like fine wine that gets better with age. This 5th edition has been expanded by over three hundred carefully documented pages. *The Rife Handbook* is an invaluable resource, not only for scientists and health professionals, but also for individuals who want to know more about technologies and adjunctive health therapies. I urge you to use this book as a guide and as a reference. Savor it.

MILBANK JOHNSON, M. D.
PACIFIC MUTUAL LIFE BLDG.
LOS ANGELES, CALIFORNIA

November 9, 1931

My dear Mr. Rife:

In the name of the other three gentlemen and myself I want to thank you for your most courteous reception and for giving us an opportunity to have a glance of your wonderful microscope. I want to say to you that we all spent one of the most instructive and interesting afternoons of our lives in your laboratory.

Upon returning to San Diego that evening I wired to Dr. Arthur I. Kendall of Chicago and gave him a brief description of what we had seen and our opinion of it, and upon my return to Pasadena this morning I received the following telegram from Dr. Kendall - "Expect to start for California Saturday night. Letter follows".

If he comes straight through, which I think he will, he will arrive in Pasadena on Tuesday, November 17 so be sure and have your microscope in perfect condition for the Big Chief when he arrives. I will bring him down to San Diego in my car at which time you and Dr. Kendall can make such arrangements as you desire.

Thanking you again for your courtesy, I am

Yours very sincerely,

Mr. Roy Rife

Introduction

Imagine what your life would be like if you could eliminate ill health in as little as one day for something mild (like the common cold), or in several months to a year, maximum, for a more serious illness (like cancer). To do this, you would need three things: a protocol to strengthen your system so that it's no longer a breeding ground for pathogens, a frequency device, and a list of frequencies to go with the device. You would not need toxic drugs or invasive surgery, you would not incur unfairly high medical bills, and you would not have to depend on doctors for long periods of time. This protocol is called Rife Therapy, named after its inventor Royal Raymond Rife.

American scientist Royal Rife, and his remarkable technology that has helped thousands overcome life-threatening diseases, is finally becoming more public after decades of suppression. As incredible as it sounds, though, the knowledge that specific frequencies destroy pathogens is not new. Royal Rife began his career as an inventor almost a century ago.

It all started with one of Rife's key inventions, a most unusual microscope. In those days, the magnifying power of existing microscopes was poor. Individual viruses, and even some bacteria, could not be seen because they were too small. Determined to view them, Rife built his highly acclaimed Universal Microscope. Many times more powerful than other magnifying instruments, the microscope made specimens visible without killing them. This feat was beyond the capacity of even an electron

microscope, which makes pathogens visible by bombarding them with electrons in a vacuum, thus destroying them.

Rife had a good reason for wanting to see specimens in their natural live state. If you want to discover how to kill a microorganism, you need to know how it reacts to its environment. Once Rife could observe the activities and responses of living microorganisms, he could devise a method to destroy them. Hence, the Rife Ray was born.

Rife's strategy of destroying microorganisms was based on the principle of resonance. Every living organism has a resonant frequency, or intrinsic radiation signature. The cliché of the soprano who shatters a glass with her single, pure, focused tone is (for now) an adequate working metaphor for how Rife's electronic device worked. The various frequencies it emitted, via an electromagnetic field, corresponded to the resonance of different pathogens and therefore disabled them. Once they were no longer viable, the body's immune cells could eliminate them.

Tests were successfully conducted on thousands of infected animals. Many of the most prestigious doctors and pathologists in the US, impressed with the initial results, supported Rife in several ways. They gave him money, worked with him in his laboratory, substantiated his findings, and used the Rife Ray in their US and overseas clinics. Some doctors even sent Rife notarized affidavits affirming the effectiveness of the treatments. Accounts of Rife's microscope and ray machine were published in newspapers, journals, and medical bulletins across the United States.

Ironically, Rife's treatments may have been too successful. The medical-pharmaceutical industry, foreseeing a massive loss in profits from drugs and surgeries, appointed some very vocal opponents—none of whom, it should be pointed out, tested the machine. The physicians and financial backers who had been Rife's colleagues and friends became targets of character assassination. Medical boards threatened to revoke the licenses of doctors who used the Rife Ray unless they relinquished their equipment. Some of Rife's closest collaborators later denied even knowing him, despite the existence of a widely circulated photograph in which they appeared with him at a banquet in his honor. Articles on Rife and his inventions began disappearing from newspaper archives. The greed and callousness of the wealthy powerful few deprived many sick people of healing and even cost them their lives. Vilified and discredited by the ignorant and greedy, his technology misunderstood and underutilized, Royal Raymond Rife died in 1971.

Rife's story, while unique in some ways, nonetheless follows a familiar pattern. First, a therapy is discovered that's non-invasive, inexpensive, and drug free. Next, after it makes large numbers of people well, its inventor, proponents and users are privately harassed, publicly humiliated, and legally persecuted. Perhaps they even die of mysterious causes or under suspicious circumstances. Finally, steeped in rumor and innuendo, the modality disappears. As with other promising complementary treatments, Rife's therapy was driven underground.

The long silence on Rife and his inventions was finally broken with Christopher Bird's article "What Has Become of the Rife Microscope?", which appeared in the March 1976 issue of *New Age Journal* and was later reprinted in other publications. Then in 1987, Barry Lynes published *The Cancer Cure That Worked*, an emotionally-charged glorification of Rife's life and work. However, original source material was scarce. Movie footage from 1936 showing Rife in his lab, and a few equally old photographs, provided the only visual clues about the equipment.

Gradually, other memorabilia surfaced: Rife's surviving lab notes, letters, telegrams, photographs and awards, all unearthed from different locations. One researcher spent hours rummaging through the morgue files of a California newspaper office to find decades-old news clippings. Another investigator spotted articles in obscure yellowing engineering journals. Still others uncovered documents in the attics and basements of people descended from Rife's colleagues and co-workers. One astonishing find was an old trunk full of reel-to-reel tapes, featuring discussions between Rife and his close colleagues. The tapes were transferred onto CDs and made available to the public.

Around 2005, a non-working Rife Ray was found in a museum and restored by a team of resourceful engineers. Shortly after, a US frequency equipment manufacturer acquired a box of priceless documents from a nurse who had once worked with Royal Rife's colleague John Marsh. This manufacturer was then given an old schematic of one of Rife's original units built in the 1930s. With the help of others—including an elderly engineer familiar with the tube technology of Rife's era—he deciphered the almost illegible drawing and reconstructed the model. Then an actual prototype of yet another model was discovered, and the Rife community was closer to understanding how Rife's technology worked. This knowledge was not merely academic. It could, and would, lead to the production of more effective modern units.

Also around this time, the most powerful of Rife's microscopes was resurrected: the Universal Microscope (after being stolen from Rife's lab decades earlier and then recovered). Kept safely in an undisclosed location, it underwent meticulous restoration by several key researchers until it was again taken. Predictably perhaps, the cloak-and-dagger antics of secrecy, theft, and duplicity that had plagued Royal Rife have continued today.

Fortunately, not everyone interested in Rife history wanted to hoard their treasures. Many documents, along with designs of Rife's original ray machine, were posted on the Internet. This global sharing has allowed Rife's diverse technologies to inspire progress in many fields of electromedicine today. Using the primary source materials as references, scientists, health practitioners, electronics engineers and curious laypeople are now experimenting with different types of machines as well as new frequencies. With a rapidly growing, fresh generation of wellness seekers demanding access to life-saving technology, a new era of frequency healing has been born.

Although frequency equipment has been substantially modified and redesigned since Rife's colleagues treated people in the 1930s, 40s and 50s, the basic principle of how the devices work—pathogen destruction through resonance—remains the same. There are now hundreds of companies, on every continent of the globe, selling frequency therapy units to address all types of diseases. Despite the intimidation tactics of the medical-pharmaceutical industry and some government agencies, more researchers are stepping forward to share what they know, via the printed page, radio, electronic media, and at conferences. In addition, medical clinics and formal and informal research centers are springing up all over the world: Australia, Mexico, Canada, the Netherlands, New Zealand, South Africa, Germany, Romania, and the United States, among other countries.

It was over 30 years ago—around 1983, long before the massive infusion of Rife-related artifacts—that I first heard about Rife’s technology. Cryptic fliers from companies specializing in unusual devices somehow found their way to me. From time to time, electronics buffs and complementary health practitioners would tell me about a device that emitted frequencies to reverse disease, but they were extremely vague in their accounts and couldn’t or wouldn’t elaborate. The couple of fliers that specifically addressed rife machines gave, for merchant contact information, addresses that were either in Mexico or for United States post office boxes, so I wasn’t sure if the sellers were honorable. Because I still had more questions than answers about the information I was seeing, I didn’t do much more than collect data.

Thus for many years, Rife and his inventions occupied the same category as all the other unsolved mysteries of the universe, like who built the Easter Island statues and how did the Bermuda Triangle sink ships. Although my collection of papers taunted me with their “too good to be true” rumors, my intuition told me that this information was vitally important and would one day bear fruit. So I put everything into a file folder and waited, remaining open to whatever the universe might choose to reveal.

Then in 1993 I met Howard, a US-based dulcimer maker and musician who had majored in electrical engineering at Cornell and was now retired. With his highly inquisitive mind, engineering background and love of tinkering with machines, Howard was an ideal Rife researcher. (He had already demonstrated an affinity for unusual science projects: One winter holiday, he sent me several Petri dishes containing glow-in-the-dark fungus as a gift.) Howard had previously been interested in frequencies as a musician (as had I), so learning about Rife was a logical next step. When he informed me that unfortunately (for experimentation purposes) he was in excellent health and therefore had no way to test his (not one, but two) frequency units, I could not believe my good fortune. Having suffered for years from a severe systemic *Candida albicans* infection and desperate for relief, I instantly volunteered to do the testing for him. Just as eagerly, Howard accepted my offer. This is how my academic query turned into a hands-on experiment.

Little did I know that my experimentation would lead me to unexpected and startling places—and continue indefinitely. I exposed myself to many different types and makes of machines and tried nearly all of the frequencies that were on the lists that came with the units.

My efforts were rewarded when the *Candida* became more manageable. Then I began helping friends and acquaintances with health problems of their own.

As people learned that I was experimenting with rife technology, they began asking me about Rife and his life, how frequencies work, and about healing in general. Not knowing all the answers—especially when they involved electronics and details about pathogens—I pumped information from every knowledgeable professional who was willing to talk to me. Dragging out my dusty medical and science textbooks, I increased my knowledge about biology, brushed up on physics, labored over chemistry, and struggled with electronics. I also read every book on Rife that I could find. The problem was, except for Barry Lynes’s indignant little paperback and one highly technical manual on how to build a frequency machine, very little information on Rife and his inventions was available. Not only that, there was no cohesive guide to understanding or using frequency equipment. Plus, information on the frequencies themselves was scattered in many different places. So I began to compile a simple guide of popular frequencies that I had personally found to be effective, while continuing to work with new frequencies.

Almost immediately, it became clear to me that I couldn’t just create a list of numbers to go with the equipment. I wanted people to understand that in most cases, it wasn’t enough to receive frequency sessions; they had to actively eliminate the conditions that had allowed their illness to occur in the first place. I needed to investigate, refine, and explain a solid, workable paradigm of what it meant to be healthy.

At that point, a major area of my life had become heavily impacted by my involvement with Rife research: my work as a Reichian (body-mind) psychotherapist. More and more clients were coming to me who were struggling not only with knotty emotional issues, but also with serious physical ailments. They had been taught that Western medicine was the only legitimate modality, so they weren’t convinced that holistic methods could help them. Some clients had trouble understanding that physical disease can influence one’s emotional state in unexpected ways. This lack of comprehension struck me as odd—considering that they had specifically sought my services because they knew that unresolved emotions lodge in the body as muscle tension, which causes biochemical changes that eventually lead to illness. But it never occurred to these same clients that many emotional problems can be exacerbated, or even directly caused, by the same biochemical imbalances and pathogens involved in disease! This piece of information even more strongly fired my resolve to focus on the physical, as well as emotional, origins of disease.

The more I became immersed in frequency therapy, sharing—with friends, acquaintances and even strangers, anyone who'd listen—became a full-time job. There was so much to report and explain that I was teaching even in social situations when I “should” have been relaxing. I did recognize, though, that this was a lot of information for people to handle—especially in a social situation, where they're not expecting to be bombarded by an impassioned lecture on medicine. Also, people tend to retain information more easily if it's written down. And, most important, although my enthusiasm never waned, my energy levels did. So I realized I needed another way to convey the material, and looked for well written, accessible books that presented the topic clearly and thoroughly.

To my great dismay, I couldn't find what I was looking for. What I wanted, very simply, was an all-purpose holistic health book that met many needs and featured a wide range of topics: cutting-edge research in medicine and science, an exposition on Rife and his work, and a foundational discussion of electromedicine (so people would understand why Rife therapy is so effective), along with a directory of frequencies to use for specific health conditions. Not surprisingly in retrospect, nothing suited my exacting requirements. After complaining for months about how hard it was to obtain reliable information about Rife, in conjunction with additional topics that I felt were essential—presented, no less, in just the way I wanted—I realized that the person who was supposed to put all this together was me. That is how my little list of popular frequencies metamorphosed into a project whose scope I couldn't possibly have foreseen. This fifth edition that you are now holding in your hands is the result of my curiosity, learning, labor and love over the course of two and a half decades.

Now that you have this *Handbook*, where do you begin? Some readers, especially those who own frequency devices, may be tempted to jump directly to the Frequency Directory (Chapter 5). But this *Handbook* is about much more than pathogen-destroying frequencies. It is about freeing yourself from medical propaganda, trusting in your own experience, and opening to the self-confidence and health that blossom when you think and act for yourself. So please don't ignore the beginning of the book. It shows you new ways to approach your body and healing, as well as addressing your questions about rife machines.

Chapter 1, “The Politics of Medicine and the Nature of Health,” is a primer on allopathic vs. holistic (also known as “complementary,” “alternative,” or “functional”)

medicine. It explains why most drugs don't work and in fact make you worse—as well as how most clinical trials are not only worthless, but can be rigged to “prove” whatever outcome the experimenter wants. The reader is also shown how drugs are approved, and by whom—which in virtually all cases, involves politics and profit rather than humanitarian concerns or even good science. This chapter also contains a brand new section on electrosmog: what it is, how it affects us, and how to avoid it.

Chapter 2, “The History of Pleomorphism and the Inventions of Royal Raymond Rife,” features Rife's unusual life and the controversial debate over pleomorphism—a phenomenon relatively unknown in the United States, but widely understood in Europe. Pleomorphism is the ability of pathogens to radically change their form, structure and function, from simple and primitive to highly complex and multi-functional, depending on the changing terrain of the body. Rife's microscope showed that often, pathogens become dangerous only when the system becomes biochemically unbalanced. So, if you are attached to the germ theory of disease, this chapter will give you a different perspective. The debate on pleomorphism is important, because as long as we perceive ourselves as helpless victims of germs, we'll continue to rely on pharmaceuticals to help us get well. But if we understand that pathogens can and do adapt to their environment, we can lessen or remove their harm, knowing that we can alter that environment—the terrain of our own bodies.

The task of making that terrain (ourselves) less hospitable to pathogens leads us to Chapter 3, “Healthy Living and Complementary Therapies.” Here, you will find some of the most effective, user-friendly, and inexpensive protocols to help you detoxify and heal. This chapter is a guide for frequency device users who want to handle the effects of sudden microbial die-off. But it's also designed for non-rifers who want clarity about lifestyle choices, and are eager to learn about some of the best, mostly self-administered, holistic protocols available today. Readers already familiar with these protocols will learn new ways to approach what they're doing. The range of therapies is vast. In addition to ozone, sauna and light therapies, Inclined Bed Therapy, and homemade colloidal silver, I have added sections on homeopathy, organ cleanses, and so-called “folk” remedies that really work—activated charcoal, clay, and castor oil. This edition also contains vital new information on food, exercise, and nutritional supplements. Also, from my Reichian psychology background, I discuss the relationship between mind and body and the psychological aspects of what we call disease.

Chapter 4 shifts our focus to the “how to” of Rife's technology. To apply this technology correctly, you need

to know who can benefit from the equipment and who should not use it, and under what circumstances; what type of frequency device might best suit your needs; how to give yourself a Rife Therapy session; how to administer sessions to children, pets and the elderly; how to select the correct frequencies; how to deal with detoxification reactions from microbial die-off; and what to do if you're not getting the results you want. If you already own a frequency device, this chapter will help you use it to its full advantage. If you don't own one, this chapter will help you choose the unit that's right for you. In addition to older material that has been rewritten for clarity, there are some new sections, including one specifically for practitioners on how to incorporate this therapy into a busy practice.

Chapter 5, offering an extensive "Frequency Directory," also teaches the reader how to navigate through the alphabetized listings that provide frequencies for common and exotic diseases. In addition to conditions such as allergies, cancer, HIV, Lyme disease, Morgellons and neurological disorders, Chapter 5 includes the viruses, bacteria, parasites, protozoa and fungi that are implicated in these symptom pictures. This chapter also doubles as a basic medical primer for the layperson; so even those without a rife machine will benefit from its contents. Summaries of the functions of organs, glands, and bodily systems accompany the listings, along with suggestions of holistic therapies that support (or can be substituted for) the frequency therapy. When medical terms are used, they are always translated into plain, everyday language.

Chapter 6, "Creating a Better World, Inside and Out," deals with topics that might be regarded as optional, but they will help us meet today's challenges. Many people are unprepared for death and they fear it, both for themselves and their loved ones. Yet paradoxically, in the United States at least, the dominant values (not to mention images) of the culture are filled with death. Our social system supports misery, poverty, fear and hate, instead of joy, abundance, truth and love. We cannot die in peace without living in love. In this chapter I discuss the changes that must be made on all levels—personal, political and transpersonal—in order for a life-based culture to emerge. In keeping with this theme, I could not resist including some exciting, groundbreaking scientific research that points to the existence of what some call "spirit" and proves beyond a doubt that love heals.

Appendix A, "Resources," lists some great sources of health-related information, products, and services (including some new listings, such as EMF protection and personal care products). For those who want to offer Rife Therapy to others, Appendix B, "Legal Implications of Rife Sessions," discusses some challenges of using a

non-medically approved device for healing purposes. (Please note that I am not an attorney. Not all countries and municipalities have the same legal requirements for providing electromedical therapies. Use this section as a guide, but do consult legal counsel to ensure that you are compliant with the laws of your locale.) Appendix C, "Healing with Electromedicine and Sound Therapies," is written for the layperson with no background in physics or electronics. This overview, which includes definitions and concepts related to the electromagnetic spectrum and sound waves, will help you better understand the more technical aspects of almost any electromedical device you wish to use.

Appendix D lists some publications on electromedicine. You may be surprised to learn that medical doctors were using many of these technologies over one hundred years ago! Appendix E describes a recent US medical study of a frequency machine to kill leukemia cells. Appendix F lists toxic chemicals in household products that many of us use every day, so you can avoid them. These chemicals are totally unnecessary because, as described in Appendix G, there are "Safe Substitutes for Common Toxic Chemicals." Appendix H shows you how to assemble your own detoxification footbath for under ten dollars (and yes, it really does work). Appendix I, compiled just before this book went to press, presents medical studies showing the harm of WiFi, microwave ovens, cell phones, computers, and other electropolluting equipment. This is a vitally important appendix, because the telecommunications industry—often with the sanction of governments, worldwide—has not only suppressed these studies (and replaced them with lies), but is now pushing the even more dangerous 5G technology. This needs to be stopped. In References, for your convenience, I include contact information for some non-mainstream sources.

Now for some editorial comments. Because a major theme of this book is self-empowerment, I have tried to select my words carefully. When referring to people with health problems, I don't use the word "patient" because it reflects and reinforces a hierarchical model that exalts the doctor as the all-knowing savior and relegates the health seeker to a subordinate, lesser role. The history of the word "layman" reveals a similar subordinate status; and even though I use "layperson" instead of the gender-biased "layman," the origin of the word should be noted. Initially, "layman" meant any person (male) who was not a member of the laity (clergy). Later, "layman" was expanded to mean anyone who was not in a specialized profession. In other words, a layman is a commoner without a title. In today's dualistic world, more respect is given to those who hold prestigious titles and degrees than to those who

do not. In truth, many laypeople are highly educated and informed—often more than those with degrees—but their lack of medical credentials apparently still makes them commoners (unworthy). I couldn't find a suitable word in English designating someone who is not a medical professional yet is worthy of respect.

This leads me to my citing of people who don't hold titles or degrees. While I have, of course, quoted credentialed professionals whom I admire and respect, I have also quoted people who aren't well known or necessarily have degrees, but who offer valuable input. Considering how many medical researchers have falsified data and outright lied (explored in depth in Chapter 1), it seems fitting that we expand our notion of whose ideas are worth considering. It is my hope that common sense and a resonance with the truth, rather than degrees and titles, will prevail.

Despite my own language preferences, when quoting others I try to respect the writer's voice. Thus, if certain words are used (such as "patient"), I leave them in. The same holds true with spellings, such as British English, which is sometimes different from American English.

Royal Rife's name is used often, as one would expect. Appropriate to this usage, "Rife" is capitalized. However, "rife" and "rifying" are now being used as verbs (referring to the act of giving oneself a frequency session). For these, and for the noun "rifer" (which refers to one who gives oneself frequency sessions), the "r" is not capitalized. Similarly, when used to describe frequency equipment, "rife" is not capitalized, as none of the units being made today were made by Royal Rife the man. A similar logic explains why "rife practitioner" also uses a lower-case "r." However, when referring to the research, "Rife" is capitalized because engineers and scientists involved in this area are usually investigating the man as well as the technology. I do capitalize "Rife Therapy," however, to make this modality immediately visually recognizable and distinct from other holistic protocols being discussed.

My final editorial comment concerns the completeness of the data in this new edition. I have included current discoveries about health as much as possible. We already know that two scientists—who for years had been ridiculed by colleagues for insisting that stomach ulcers are caused by a bacterium—found *Helicobacter pylori* in the stomach lining of enough people with ulcers to win a Nobel Prize. However, dangerous microorganisms are now being linked to conditions we normally might not associate with pathogens at all. For example, one doctor found a corkscrew-shaped, bacterial spirochete in the spinal fluid of over 90% of his clients with Multiple Sclerosis. Actinomycetes is being tied to Parkinson's

disease. And irrefutable evidence shows that not one, but two strains of Adenovirus can make us fat. In addition, we now know that bones and fat cells produce hormones.

More details on medical cover-ups have also been included in this edition, although frankly, it's hard to keep up with them. There's a fresh scandal every month, if not week—about not only the adverse effects of drugs, vaccines and medical devices, but also the drug industry's attempts to hide, distort and outright falsify test results in the hope that consumers will continue to buy their products. Depending on the media spin, it's either sloppy science (their intentions are honorable and they're just incredibly incompetent), or outright lies (they know exactly what they're doing and don't care who they hurt). Every effort has been made to bring you the most up-to-date news. But unfortunately, more corruption always seems to occur (or at least becomes public knowledge). The printed page cannot match the speed at which electronic media disseminates new information. Therefore, you are encouraged to search for updates on your own.

The first edition of *The Rife Handbook* debuted at the March 2002 Rife Conference held in Las Vegas, Nevada, in the United States. Despite my having steadily been researching this technology for eight years at that time (long after I was given those first fliers about Rife's therapy), I could not have anticipated how many people were hungry for information about this unique healing modality. Nor could I have grasped the diversity and sophistication of knowledge required to be a researcher in this field—not until I attended the conference.

Being at that conference, as a speaker, author and student, changed my life. Health professionals, equipment manufacturers, and engineers were present. But others attended too—people who knew someone with a serious disease or who were ill themselves. Tired of the same old drugs-and-surgery routine dispensed by doctors trained in nothing else, they wanted something better. Several people who were already using the technology recounted successful interventions against cancer, Lyme disease, and other conditions. I was very moved by the courage of these folks who were taking charge of their own lives—often despite the hostility of their friends and families, and against the advice of their allopathically trained doctors.

I was also impressed by the dedication and talents of the researchers. While it was true that they could be a cantankerous bunch—quarreling about their pet theories, how things worked and how to best accomplish their goals—it was largely because they cared. They

cared not only about whether others lived or died, they also cared about the quality of people's lives. As I later discovered, many of the researchers (like me) had at some point struggled with severe ill health. Others began their research after the death of a close friend or family member.

As I listened to the presentations and saw how much there was to learn, it was hard not to feel overwhelmed by what the seasoned rifiers knew. The field of Rife technology is so vast, it requires the knowledge and expertise of people in many diverse disciplines: the healing arts (medical doctor, acupuncturist, homeopath, naturopath, veterinarian, massage therapist); medical and scientific research (microscopist, laboratory technician, microbiologist); historical research (archivist, writer, filmmaker); physics; and of course electronics engineers, with their nuts-and-bolts skills of building equipment. Every rifer has something to contribute. This technology could not have come this far without input from everyone.

In the years since the first—and, in hindsight, very elementary—edition of this *Handbook* was released, I've had the almost daily privilege of connecting with customers from all over the world: Australia, Austria, Belgium, Brazil, Canada, China, Croatia, Denmark, France, Germany, Greece, Hong Kong, India, Israel, Italy, Japan, Kuwait, Manila, Mexico, the Netherlands, New Zealand, Norway, Pakistan, Poland, the Philippines, Romania, Singapore, Slovenia, South Africa, Spain, Sweden, Switzerland, Thailand, United Arab Emirates, United Kingdom, Zimbabwe, and of course my native United States. Words cannot adequately describe my appreciation of these rich multicultural exchanges. The health professionals wanted to learn more, do more. And laypeople, many of them quite ill, made a point of telling me how rigorously they had been seeking alternatives to the unhelpful medical treatments they had already tried. We may not be regularly reading or hearing about Rife's inventions in the national media, but that has not prevented knowledge of this therapy from spreading. People are waking up. They are intuitively sensing that frequency healing is a viable option, despite disparaging comments from the mainstream press. And these seekers won't stop searching until they find something that works.

Knowing how to operate frequency equipment and which frequencies to use is a good start for your health protocol. But genuine healing usually requires major changes. This is why *The Rife Handbook* contains more than the three chapters that deal with the history of Rife, the “how to” of his therapy, and the “which frequencies

should I use” advice. You are being asked to set aside a one-size-fits-all, pop-a-pill-for-instant-results mentality concerning medicine. You are also being asked to consider that your education in the sciences was at best incomplete, and at worst an outright lie. You are being asked to maintain (at least for a while) an open and inquiring mind. And you are being asked to make changes in your lifestyle if necessary. This could mean anything from different dietary habits to questioning authority or even to meditating daily. Transformation means thinking outside of the box—indeed, dismantling that box entirely! As a colleague said to me recently, “*What box?* There is no box!” The good news is, the more we extricate ourselves from old habits and rigid constraints, the more we can reinvent ourselves in increasingly life-affirming ways.

This new paradigm that I am asking you to consider does contain some familiar elements. After all, Rife's therapy—at least what he publicized—was all about viewing and devitalizing harmful microorganisms. But despite the clear association between pathogens and disease, this doesn't mean that we should ignore other issues pertaining to wellness. Healing means balancing the bodily terrain; even Rife himself stated its importance. (Hence, the need for lifestyle changes.) Also, despite Rife's spotlight on pathogens, we are realizing today that his therapy very likely conferred other benefits unrelated to pathogen destruction. The field created by his ray machine appears to have helped normalize tissue function. For many reasons, then, it's a mistake to utilize Rife's technology in an allopathic way.

Nevertheless, I do not intend to misrepresent Rife Therapy. Despite the amazing cures witnessed by Rife's colleagues, or how much I have personally benefited, or the many remarkable success stories reported by friends, colleagues and acquaintances, I freely admit that even an outstanding therapy has its limitations. There is no magic cure-all that has been found to work for everyone, always. While the majority of people respond favorably to sessions, some respond minimally or not at all. The machines cannot produce miracle cures; your body is in charge of that. If you faithfully give yourself rife sessions but continue doing what contributed to your getting sick in the first place, the best equipment in the world will not produce lasting positive changes. Also, *when* you use a healing modality is as important as the therapy itself. Depending on the extent and type of imbalance, one protocol may work better at a given time than another.

Sometimes I hear people complain when their healing is not progressing according to schedule. But whose schedule? We are not machines, even though the medical establishment would like us to believe that we are.

Furthermore, the medical industry has a very narrow definition of “normal,” even though people vary wildly outside the range of presumed “normalcy.” How many times have you heard of someone who felt unwell, only to have their doctor say, “There’s nothing wrong with you; you’re in perfect health”? We need to rely on common sense and how we feel, not blindly trust medical biases that have no foundation in fact. Much of modern medicine is based on arbitrary standards that change, according to the desires, agendas, and goals for profit of those in power.

Here’s a question, then, that I like to ask: If medical standards keep changing (apparently capriciously), and doctors keep changing their minds about protocols and prescriptions (based on these capricious standards), whose standards should we follow? And from whom should we seek guidance? Maybe it’s time to reevaluate the health care you have been receiving. Consulting with a health professional can be helpful and even essential, but you must use your own discernment too. Who is most qualified to help you? The person with the most impressive credentials may not be your best choice. If your practitioner doesn’t listen to your concerns or take them seriously, or if his or her training seems more important than what you are experiencing, maybe you should start looking for another practitioner.

You are the one who’s living in your body—so ultimately, your best teacher is you! However, to become that exemplary teacher requires commitment. You have to study, reason, decide what to keep and what to discard, trust your own (informed) experience, and be willing to make mistakes and learn from them. And you *will* make mistakes! But let that be okay. Taking responsibility and being accountable for our own decisions and actions makes us powerful. This book is a stepping stone to acquiring the knowledge that you need to become an expert...on you.

Today, five decades after Rife’s death, the concepts of Rife Therapy, frequency healing and resonance therapy—while not yet household phrases (at least in the US)—are trickling more into the public’s consciousness. In some circles, the technology is being used so regularly that the word “rifting” has become a verb. I think that Royal Rife would have been moved and gratified that his modality is finally being given the respect it deserves. I trust that by the time you finish this book, you, too, will be using the word “rifting” as a verb.

One final thought. More and more people are insisting that they aren’t commodities that are bought and sold in the marketplace. They don’t want to be toyed with, experimented on, or lied to. They don’t want their

treatment options limited by what their doctors were allowed to learn in medical school. And they don’t want licensing boards to prevent their own doctors from helping them: most boards forbid doctors to suggest alternatives to the prevailing (allopathic) standard of care.

People also want their health care providers to honor their need for compassion and hope as much as they honor their need for physical care. Health seekers want to be respected, to have their humanity acknowledged—and to be free to make their own choices. In other words, people want a voice in matters that affect them—and this includes the health protocols they use. No wonder polls consistently show that three-quarters of the United States population have sought complementary therapies in addition to Western medicine!

In this technologically advanced and uncertain age, with escalating infectious diseases and degenerative conditions, we need Rife’s and similar technologies more than ever. Yet the power elite is fighting back even harder, invested in perpetuating its own agenda and maintaining the status quo—at the expense of health and happiness, not to mention lives. Despite an obvious need worldwide for all kinds of electromedical modalities, information about Rife Therapy has largely been available only to the few who discover it by chance, or who know where to look for it (and to look for it at all). The majority of people in the United States are ignorant of this elegant technology that can substantially reduce suffering and save countless lives. My goal is for *The Rife Handbook* to empower significant numbers of people—not only by providing them with reliable information about more and better health care choices, but by inspiring them to spread the word to others that these choices exist.

The widespread use of frequency therapies, including Rife’s technology, promises to change the way medicine is practiced. Even if you are fortunate to be in good health now, it’s comforting to know that this technology is available if you or a loved one need it in the future. Simply by picking up this book, you have proven that you want more than what’s being offered by industrialized pill pushers, that you aren’t satisfied with the lowest common denominator of mediocrity. Anyone who seriously investigates Rife Therapy is making a statement. Therefore, you deserve to be congratulated for having the vision and strength to see through—and beyond—the dominant paradigm. It takes courage to challenge entrenched ideas!

I sincerely thank you for helping to create this positive global change in consciousness. It is truly a blessing to be accompanied by all of you who are embarking on this amazing journey of healing and hope.

The Campaign to Suppress Holistic Medicine

How did medicine in America shift from its early emphasis on prevention and health to a model of disease management?

In 1908, the American Medical Association's newly formed Council on Medical Education wrote to industrialist millionaire Andrew Carnegie to propose a collaboration to "reform" medical education. The Carnegie Foundation was allied with the Rockefeller family, which had interests in oil and was now investing heavily in pharmaceutical companies. The group decided to hire Abraham Flexner to investigate medical schools in the United States and Canada.

Flexner was a schoolmaster who knew nothing about the field of medicine. However, his brother Simon was director of the Rockefeller Institute for Medical Research. It's no surprise, then, that Flexner's findings—commonly known as the *Flexner Report*—heavily favored those medical schools that emphasized the use of pharmaceuticals. Wanting to improve the status of doctors, Flexner suggested closing most of the schools that allowed entry to women and black people. He advised the medical field to require specialization. And he insisted that funding and accreditation be given to only those medical schools that trained doctors in emergency and surgical medicine—both of which require the extensive use of drugs.

In response, the *New York State Journal of Medicine* berated the Carnegie Foundation for being dictatorial, for attempting to eliminate specific universities, for threatening the freedom of whatever medical schools were being allowed to remain open, and for denigrating anything that competed with the prevailing allopathic (Western, drug-oriented) methods. However, most other medical organizations and publications praised the Carnegie Foundation's goals precisely *because* of the clear bias against chiropractic, homeopathy, and all other forms of holistic medicine. The *Journal of the American Medical Association* supported Flexner's position as truth. Soon, the historic *Flexner Report* was widely acclaimed by everyone in the allopathic medical community. One hundred sixty medical schools had been open in 1905. But by 1927—just seventeen years after the *Flexner Report* was issued—that number dropped to eighty.

The Rife Handbook of Frequency Therapy and Holistic Health is designed to challenge this legacy of suppression and deception. We don't have to perpetuate what we have inherited. It's time to replace establishment medicine with true healing, derived from many disciplines.

Nearly all people die of their medicines, and not of their illnesses.

The Politics of Medicine and the Nature of Health

TODAY'S CHALLENGE

Chances are, if you're reading this book, you have a health problem. Or someone you know does. Perhaps your treatment didn't work. Or it had too many unwanted, negative effects. Maybe it's taking too long. Are there viable alternatives for you, your family and friends? What are these other modalities, and how can you access them?

Perhaps you've heard about Rife the man, or the therapy he invented. What is it, how do you use it, and how can you get it—now? If you suffer from chronic or serious health problems, it's understandable that you might feel impatient and want answers to these questions immediately. This chapter doesn't talk about Rife or his therapy, though. Why not?

Electromedicine, which includes Rife Therapy, is not routinely used. It's not routinely used because it's not well known. But this doesn't mean it doesn't work. The relative obscurity of all electromedical modalities is due to the overbearing nature of our current medical paradigm.

In order to utilize Rife Therapy properly, it's important to understand the limitations of our medical system and why it has eclipsed other, more effective modalities. Therefore, I ask for your patience as I present the material in a manner to provide you with maximum benefit.

Some of the data that you'll read may surprise, disturb, and even shock you. But only by knowing the truth can we know what we're dealing with in our quest for healing. The truth always helps us make wise and informed choices.

Everyone wants to be healthy. Yet in this modern world, good health seems more elusive than ever. The number of chronic and degenerative diseases, such as arthritis, diabetes and colitis, have skyrocketed. Cancer, which according to the American Cancer Society afflicted only one in 8,000 people living in the United States in 1901, now plagues almost one out of two Americans.¹ Many more people suffer from asthma and food allergies—which, although usually not life-threatening, can substantially interfere with one's quality of life.

Citizens of industrialized countries outside the US have fared better, at least so far. However, with the rapid increase of "fast" food, as well as unwise agricultural practices and pollution worldwide, the prevalence and severity of illnesses outside the US is escalating as well. And many people in non-westernized countries suffer from serious diseases and microbial epidemics, most of which are caused by unsanitary living conditions. Despite our apparent best efforts, viable long-range plans to improve the world's health have not yet appeared. Global illness is an escalating and severe problem.

It's time to change our approach—but so far, the world has been given basically one perspective: the dominant medical model. Do we really have other options?

We do. However, to explore these other options, we need to take a critical look at the existing medical paradigm. Once we understand what went wrong, we can figure out how to make it right. Then, global illness will become global wellness.

DEFINING HEALTH

The word *healthy* comes from an old Anglo-Saxon word meaning “to heal, make whole.” This indicates that health is the ability to function in a unified way, in which all parts and living processes interact with each other in a complex, balanced exchange.

We cannot be robustly healthy in general while some little part of us is very ill, just as individual parts of us cannot be in perfect health while the rest of the body is sick. How many times have you heard, “She was *perfectly healthy* until she came down with cancer”? That “perfect health” didn’t exist. It took *time* for that woman to reach a state of imbalance. Her doctors and family just *thought* she had been well because they were unable to recognize the warning signs that indicated the eventual onset of cancer. The limitations of conventional medical training impeded not only the ability to diagnose, but also to cure.

There are two basic approaches to disease: allopathic (modern Western) medicine, and holistic (complementary) care. Holistic medicine is sometimes called “functional medicine” because it deals with the function and structure of the body, and not just pathology, infection and disease. Most of us have been raised under an allopathic paradigm; but with a little practice, you can expand out of the allopathic world into the wider arena of holism.

Allopathic medicine is concerned with treating disease. It regards the body as a machine that is the sum of its parts. If something breaks, it must be fixed. One way to fix it is to cut out the body part or parts that aren’t working (surgery). Another way to fix it is to give the person a drug that substitutes for the function of the body part or parts that aren’t working. Still another way to fix the body is to numb the person against feeling the uncomfortable symptoms—again, by administering drugs. Drugs are created by extracting individual components from whole herbs, and/or synthesizing chemicals in a laboratory.

Holistic care is concerned with maintaining health. It treats the person as a living entity of interconnected relationships rather than as a carrier of isolated symptoms we call *disease*. The body is a unified organism that is greater than the sum of its parts. If something doesn’t function properly, we need to find out why. Improving function requires a multi-dimensional approach. We must eliminate the poisons that clog the system. We also require the appropriate raw materials to rebuild tissue. These include foods, herbs and perhaps supplemental nutrients. And we might benefit from energetic treatments—in the form of healing electromagnetic fields, electricity, or magnetism—which encourage proper function of cells.

There are times when allopathic medicine does have its place. If a motorist is seriously injured in an

automobile collision, doctors can perform life-saving surgery. If someone does not produce enough insulin (a pancreatic hormone that helps the body utilize blood sugar) and is about to fall into a dangerous diabetic coma, the administration of an allopathic drug can save a life. Emergencies by definition require immediate intervention; we don’t have time to wait for the body’s natural recuperative abilities to start working and create the needed changes. It is wise to acknowledge that sometimes, the body simply cannot heal without a well-timed, externally-generated push.

Degenerative diseases, however, take time to develop. Had the person possessed more biochemical and energetic balance in the first place, s/he would not have reached the point of requiring such drastic intervention. Restorative steps could have been taken initially so there would not be a sudden need for insulin later. With allopathic medicine, invasive behavior is the norm and not the exception. With preventive medicine, there is less need for aggressive intervention because the body’s innate ability to heal is being respected instead of suppressed.

In America, allopathic medicine is called “traditional,” while holistic medicine is commonly labeled “alternative.” But it’s allopathic medicine that is “alternative.” Holistic medicine has existed since ancient times, while allopathic medicine has gained gradual prominence only in the last century.

As part of this attempt at cognitive reversal, allopathic medicine is also called *mainstream* care. Being in the *mainstream* (as compared to an incidental little trickle) implies *main treatment*, which then translates to *treatment of choice*. But one must ask, “Whose choice?” Not surprisingly, *mainstream* medicine is heavily promoted by *mainstream* media, which casts holistic care as the “other” or “alternative” modality—and, by implication, as “secondary” or “inferior.” With few exceptions, the media also tries to denigrate holistic care through such misleading terminology as “controversial,” even though the mainstream press itself has reported that about 75% of the United States population has tried some form of “alternative” holistic modality in the past several years. In *Immunization: The Reality Behind the Myth*, Walene James asks:

What is *controversy*? The word itself comes from the Latin meaning “turned opposite.” That which is controversial is turned opposite a dominating structure, in this case, establishment medicine. In a free and open society, there would be no such label as “controversial,” only disagreement within an open forum of ideas and options. There would be no one mainstream but many streams, each meeting different needs.

Likewise with the word *alternative*, as in “alternative” medicine. What if we called [the] Spanish [language] “alternative English”? The ethnocentrism—or is it chauvinism?—would be obvious.²

People conditioned by the Western medical model view it as *the* method of healing; they follow its dictates without question. What if there were more options, models that helped us take responsibility for our health rather than give away our power to question and choose? What if there were models that helped us unearth potential we never knew we had?

The first step, then, to managing disease is understanding what it means to be healthy. What is health? Health reflects an organism’s ability to grow and function at optimal physical, emotional and energetic levels according to its nature. A healthy organism radiates vitality or life force. It assimilates, transforms and redirects life force—either back to itself when necessary, or outside of itself. In biochemical terms, this organism absorbs nutrients, utilizes them for repair, transforms them into fuel for energy, and removes toxic wastes that are a byproduct of metabolism. Emotionally, the individual reaches out to the environment (including other people), absorbs what is optimal for growth, and then gives back to the environment in an appropriate manner, while maintaining appropriate and flexible boundaries.

An unhealthy organism does not radiate vitality. It cannot adequately or efficiently utilize life force for its growth. Lacking energy to give to its environment, it tries to draw energy to itself. When extreme depletion occurs, this state is known as disease, reflecting an organism’s inability to optimally function and grow. Such an individual may also be emotionally restrained.

Randolph Stone, founder of Polarity Therapy, once pointed out that one’s level of health depends on a free flow of energy in the body-mind system:

When these energy currents flow freely without interruption there is a state of balance, . . . [a] freedom of motion and function, called health. . . . Interference in this natural flow of energy manifests as a multitude of pains and symptoms of energy blocks, where the current is short-circuited and broken down. This is called “disease,” named after the structure plus “itis” (inflammation) or “algia” (pain), such as appendicitis, neuralgia or a complete breakdown “lysis,” like in paralysis.³

People out of balance must work harder to maintain themselves. There is less efficiency and enjoyment in everyday activity. Eventually, the decrease of overall

It is much more important to know what sort of a patient has a disease than what sort of a disease a patient has. . . . The good physician treats the disease; the great physician treats the patient who has the disease.

vitality takes its toll: if the imbalance is severe enough, or occurs over too long a period, degeneration begins.

There are different levels of being ill or out of balance. Some common categories are *physical*, *emotional*, *mental*, *energetic* and *spiritual*.

Physical imbalance is the easiest to spot. Nausea, fever, or a sprained ankle may be characterized as physical. Examples of emotional imbalance include unrelieved upset, manic excitement, or uncontrollable rage. A mental imbalance often corresponds with emotional affliction, but disordered thinking such as obsession can be assigned to the mental arena for now. For those focused on practical, concrete reality, energetic imbalances may be more difficult to detect or even accept as factual; but they can be regarded as blockages that prevent limbs, organs, glands, or entire systems in the body from functioning correctly.

The last imbalance on my list, spiritual, can admittedly be difficult to identify. Spirituality is a very personal experience, and it means different things to different people. I define it for myself as “the consciousness of All That Is, that gives people the feeling of love and support through any experience.” An example of a spiritual imbalance is someone who feels depressed, lost or unloved because s/he doesn’t feel connected to a larger community outside of self.

The ways in which these five areas of imbalances overlap are many and complex. In fact, sometimes the structural, biochemical and energetic aspects can be difficult to separate. Acupuncturists who take the client’s energetic pulse, and chiropractors who use kinesiology (muscle testing), are familiar with the relationships between structural weaknesses in the body involving muscles and bones, and imbalances in apparently unrelated organs and glands. For example, an injured ankle may not simply reflect an isolated mechanical injury, but the end result of a weakened digestive system, as the pathways of the liver and gall bladder meridians run on both sides of the foot.

Another example of overlap is a queasy stomach and vomiting—classic physical symptoms of indigestion. However, there may be an emotional component as well.

Let's say a person is feeling upset due to a difficult situation. Neurologically, the message of upset is conveyed via electrical impulses that travel from the brain down the spine to the digestive tract. This causes the stomach to contract, interfering with the flow of digestive juices—which in turn hinders digestion, perhaps even to the point where vomiting may occur. Now add worry to the mix. If the person is obsessing (a mental function) about something upsetting that *might* happen, this “critical mass” of both mental and emotional distress may not only fuel indigestion, but cause the colon to become inflamed (a situation we refer to as a disease called “colitis”).

The biochemical and the neurological are acutely intertwined. In her groundbreaking book *Molecules of Emotion*, neuroscientist Candace Pert reported that receptors to “brain” chemicals called *neurotransmitters* are found not only in the brain, but also in the intestine walls. In fact, about 80% of the body's so-called brain chemical serotonin is produced in the gut! Thus, a “gut” feeling, unexplainable by the rational mind, is experienced literally and viscerally by the gut, and not just in the brain.

Again using the example of indigestion, other energetic pathways may be involved. The major acupuncture meridian that runs vertically down the midline of the body, through the belly, could be overactive or depleted of energy, and thus play a causal role in indigestion. The converse may also be true: injury or a constricted digestive tract, perhaps due to mechanical blockage, can create an imbalance in a meridian where none had existed before.

Finally, spiritual difficulties may play a part in this condition. People who don't feel loved or connected to others tend to be emotionally depressed. The depression may not be conscious, but it depletes the body of vitality. The body doesn't function optimally because there isn't enough energy to nourish all the cells. Collapse occurs, leading to all kinds of physical symptoms. So, even though spiritual imbalance is more conceptually amorphous than the other categories, it's the most encompassing. What began as a presumably simple symptom, indigestion, proves to be a complex, interweaving affair.

Classifying symptoms as belonging to “body,” “mind,” “emotions,” “energy” or “spirit,” is, in a way, reductionist. However, we have to start somewhere in this complex maze of cause and effect if we want to address the imbalance. This *Handbook* focuses (though not exclusively) on the physical body as the primary reference, or starting point, in the vast field that some refer to as mind-body-spirit. When the physical body becomes obviously disrupted, we call the resulting imbalance “disease.” Let's look at the many factors that contribute to illness, so we can get to the roots of the problems and fix them.

HOW WE BECOME ILL

From a holistic perspective, there are “contributors to” disease rather than “causes of” disease, because illness is rarely associated with a single factor. Rather, illness consists of many interrelated factors.

Nutritional Deficiencies

Nutrient starvation is due to poor quality food. Most people eat a diet consisting largely of processed food loaded with chemical additives. In fact, it's debatable whether some items sold to eat should be called “food” at all. A diet guaranteed to cause nutritional deficiencies—literally, the starvation of the body's cells—includes refined or excess sugars; refined carbohydrates (breads, pastries and pasta, made from denatured grains); chemical preservatives, flavorings, dyes, and other artificial additives; unfermented or improperly fermented soy products; soda and fruit juices; so-called junk food (such as manufactured dried snacks and chips); pasteurized and homogenized dairy; and most vegetable oils. A better term for such items is “fake food.” I would also include glutinous grains in this list, even if they are whole and not refined.

Fake foods do more than merely deprive the body of what it needs to thrive. They leach valuable nutrients from every cell. They add harmful toxic compounds, causing even more depletion in the system. And they hinder the body's ability to resist internal and external assaults and injuries. Under these conditions, digestion, absorption and assimilation of even healthful food is difficult. For a detailed discussion of food and diet, see Chapter 3.

Sleep Deficit

It's crucial to get at least seven hours of sleep a night, and preferably at least eight. The body uses the time to repair itself. Waste removal continues even more efficiently because tasks that are normally done during waking hours have been set aside. Vital functions such as heartbeat and respiration slow to a minimum. Even the brain is working to restore itself and promote memory retention.

Illness, nutrient starvation, hormonal problems, and irregular lifestyle habits can all contribute to a lack of sleep. Conversely, when we don't get enough sleep—and especially if sleep deficit continues over a period of even a few days, not to mention months and years—we lay the foundation for vastly reduced functioning, and even illness.

For a detailed discussion on the benefits of sleep, the effects of sleep deprivation, and suggestions on how to get a good night's sleep, see Chapter 3.

Oxygen Insufficiency

Oxygen scarcity is a serious problem. Not only would we die without it, but our tissues require oxygen for repair. As most pathogenic microbes thrive in an anaerobic (oxygen-deprived) environment, oxygen deprivation has serious consequences on many levels.

Some people who visit high altitudes—say, 5000 feet or higher above sea level—suffer from what is referred to as “altitude sickness” due to the lack of sufficient oxygen. Symptoms include heart palpitations and pain, migraine, insomnia, nausea, weakness, fatigue, and even fluid in the lungs in the most serious cases. A habitual lack of deep breathing (often due to the repression of painful emotions, discussed later in this section) also contributes to a lack of sufficient oxygen in the system.

In the United States, oxygen is sometimes administered to help ease conditions such as asthma and emphysema; and hyperbaric oxygen is (less often) utilized to help people recover from injuries and neurological damage. However, in many countries outside the US, the more powerful and sophisticated relatives of oxygen—ozone therapy (using pure medical grade ozone) and food grade hydrogen peroxide—are regularly employed for many different kinds of infections. Each provides significant benefits when used properly. Chapter 3 discusses in detail the history of oxygen therapies, how and why they work, and in many cases, how to administer them yourself.

Chemical Toxicity

Toxin literally means “poison.” Any substance that stresses the system’s biochemistry to the extent that cell structure and organ function are negatively affected, may be considered a poison. We call some of these foreign chemicals “drugs”—but there are literally tons of other chemicals that are so commonplace in our daily lives, and thus regarded as so normal, that many people don’t consider them dangerous. These chemicals enter the body through the skin, respiratory tract and gastrointestinal tract. The following data from *The Holistic Handbook of Sauna Therapy* describes just a few of the dangerous chemicals in our environment.

- ◆ *Benzene*. In cigarette smoke, gasoline, inks, oils, paints, plastics, rubber, detergents, explosives, pharmaceuticals and dyes. One study estimates that 45% of benzene exposure comes from cigarettes, including exposure to secondhand smoke.
- ◆ *Chloroform*. In cleaning solvents, floor polishes, insecticides, artificial silk and lacquers.

- ◆ *Dichlorobenzene*. In deodorants, insecticides, metal polishes, moth proofing, lacquers, and paints.
- ◆ *DDT (dichlorodiphenyl-trichloroethane)*. A highly toxic pesticide, it was outlawed in the United States in 1972, but can still be found in soil and other substances, including carpeting.
- ◆ *Formaldehyde*. In nearly all indoor environments: foam insulation, particle board, pressed wood products, grocery bags, waxed papers, facial tissues, paper towels, wrinkle resisters, adhesive binders in floor coverings, backings on carpet, even cigarette smoke.
- ◆ *Hexane/Heptane/Pentanes*. In glue, cement, adhesives, paint thinner, plastics, gasoline, ink.
- ◆ *Toluene*. In petroleum products, carpets, carpet glue, copy paper, paint.
- ◆ *Trichloroethylene (TCE)*. More than 90% of the TCE produced is used in dry cleaning and metal degreasing. The remainder is in printing inks, lacquers, varnishes, adhesives and paints. The National Cancer Institute lists TCE as a liver carcinogen.
- ◆ *Xylene*. In rubber, paint, ink, photo processing, plastics, insecticides, petroleum products.⁴

It’s impossible to avoid chemicals. “Our bodies act like sponges, absorbing the chemicals to which we are exposed,” write the authors of *Natural Detoxification*. “Water-soluble chemicals are absorbed and then excreted [but] fat-soluble chemicals accumulate in our fat cells and cell membranes. . . . When the body is under stress”—as during illness, emotional anguish, or nutrient deprivation—“it releases these chemicals from the fat to circulate in the bloodstream. Later, these chemicals will return to the fat cells and cell membranes, to be released another time. The release and return cycle of these chemicals continues indefinitely unless we help our bodies rid themselves of toxins.”⁵

A study on chemicals found in the human body states: “Over four million distinct chemical compounds have been reported in the literature since 1965, with 6,000 new compounds added to the list each week. “More than 3,000 chemicals are deliberately added to food and over 700 have been identified in drinking water. . . . Over 400 chemicals have been identified in human tissues, with some 48 found in adipose [fat], 40 in [breast] milk, 73 in the liver, and over 250 in blood plasma.”⁶ Less than half of these toxins have been approved by US government agencies.

The negative effects of toxic chemicals are outlined in Appendix F. Sauna therapy, along with other methods to help eliminate this toxic load, are discussed in Chapter 3.

Electron Deficiency

Charged subatomic particles called *electrons* provide energy to every cell in the body. One doesn't normally think of electrons as nutrients, but they are—because in many ways, our bodies are electrical circuits. Part of a cell is like a semi-conductor: it *conducts* electricity. The cell membrane is a capacitor: it *stores* electricity. The membrane is also a liquid crystal resonator that *detects and receives specific signals* (frequencies). Cells also emit radio waves, microwaves, infrared waves, and biophotons.

If a cell membrane is not recharged, the entire cell starts to malfunction. *Chronic disease is always associated with a loss of electricity (electrons)*. Note that if the thyroid gland—which is the body's metabolic engine—is underactive, the body cannot store enough charge and thus has a difficult time maintaining good health.

Electron *stealers* include dry wind, synthetic fabrics in clothing, negative emotions, a diet of fake food, and electrosmog (see Insert, “Electromagnetic Fields and Your Health”). Electron *donors* include moving water, natural fibers, positive emotions, a diet of raw organic vegetables and sprouted seeds, and biocompatible electromedical devices. Walking barefoot on soil, sand, rock or vegetation—as opposed to concrete, vinyl or carpet—is another way to receive free electrons from our planet Earth that's constantly recharging us.

Electromagnetic Toxicity

To many people, the word “toxin” means dangerous environmental pollutants and chemicals such as pesticides, fake foods and drugs. While chemicals certainly burden the body and prevent it from functioning properly, harmful electromagnetic (EM) fields are another, very real, and often hidden source of environmental pollution that can cause unlimited damage and even death. Some EM fields are benign or beneficial, but the majority are destructive. Of these, most are not naturally occurring; and they're caused by electronics. EM pollution is the new disease of the 21st century. For details, see Insert, “Electromagnetic Fields and Your Health.”

Weather Challenges

Weather has a profound effect on living organisms. Twenty percent of the population is estimated to be especially sensitive to certain types of weather. However, based on my personal experiences and observations, I believe that the percentage is higher—even though people may not always recognize what it is to which they are reacting.

There are many weather-related causes of discomfort and even ill health. The most obvious are extreme levels of dryness or humidity, heat or cold. (Not everyone, though, agrees that intense cold is harmful. Dutchman Wim Hof has developed a program involving breathing exercises

and repeated exposure to cold water for increasingly long periods. Scientists have found that developing the body's tolerance to cold restores mitochondrial and tissue function, improves immunity, decreases inflammation, alkalizes the blood, and activates the burning of fat. See wimhofmethod.com for more information.)

Thunderstorms are especially problematic for some people and many animals, who respond adversely to the excessive prior buildup of positive ions in the air—not to mention

the often sudden changes in barometric (air) pressure. People with arthritis are especially susceptible to changes in barometric pressure. Sensory nerves in their joints (which lack the normal cushioning from cartilage) hurt when the atmosphere changes from dry to moist, as during a storm.

Weather conditions determine the presence or absence of electrons. Moving air (such as a dry desert wind) steals electrons from the body, while moving water (such as a waterfall) replenishes electrons. Dry wind can exacerbate or outright cause asthma, hay fever and similar conditions because positive ions cause an increase in stress hormone production. Conversely, negative ions contribute to an increase in feelings of well-being and more rapid recovery from illness. Sunspot activity increases solar wind, which causes magnetic storms in the Earth's atmosphere that adversely affect the magnetic fields in our bodies. Lack of sufficient sunlight causes depression (see Chapter 3, **Light and Color**, for an in-depth discussion).

Getting Well Without the Doctor's Help

Many amazing reports have been recorded and continue to be recorded, in the lore of progressive cancer treatment. The medical establishment handles these in one of the following ways:

1. They are ignored;
2. They are explained as “anecdotal,” implying that they are lies [or they don't count, since the doctor had no control over the outcome];
3. They are said to have undergone “spontaneous remission,” i.e., unexplained recovery (this means the doctor has no idea what happened);
4. They are said to have recovered from the delayed effects of conventional (allopathic) therapy, which was administered weeks or months before the progressive therapy.

Electromagnetic Fields and Your Health

A Crash Course on the Electromagnetic Spectrum

There are many types of electromagnetic (EM) fields, collectively known as electromagnetic radiation. In this nuclear age, when one hears the word “radiation,” it’s easy to think of a dangerous nuclear powered reactor. *Radiation*, however, is simply of energy emitted by a source—whether that source is a nuclear power plant, the sun, or an electrical socket. Radiation can be harmful, beneficial or neutral.

The EM spectrum consists of energy oscillations, or *frequencies*, that comprise our (conventionally) known universe. Slow-moving EM radiation has longer wavelengths and fast-moving EM radiation has shorter wavelengths. These wavelengths are measured in cycles per second, or *Hertz* (abbreviated *Hz*). A given amount of space that contains a single low frequency can contain many high frequencies, as high frequencies have shorter wavelengths.

Electromagnetic energies include different types of electricity, radio frequencies (a huge category that’s further divided into AM radio, FM radio, TV and microwaves), infrared radiation (which includes a narrow band of far infrared), visible light, ultraviolet, X-rays, and gamma rays. Even though these energies seem unrelated to each other, and we typically think of them as separate phenomena, it’s important to understand that all EM radiation exists along a *continuum*. The various EM wavelengths exhibit different characteristics—and we use them differently—according to how quickly or slowly they’re oscillating. A chart of the EM spectrum is on the next page.

Most EM wavelengths are invisible to the human eye, and are usually undetectable to our other senses. For example, we cannot see radio waves, microwaves, infrared or ultraviolet radiation. However, the small section (band) of the electromagnetic spectrum that we can see, we call “visible light.”

Electricity and magnetism are intimately related to each other. Wherever there’s a flow of electrical current, a magnetic field is present; and wherever there’s a magnetic field, it’s possible to create an electrical current. The bodies of humans and other living things contain both electrical and magnetic energy.

EM energy can be natural or artificially produced. For example, the EM radiation that’s emitted by our sun, and which travels through space and Earth’s atmosphere, occurs naturally. It has very different properties than the more concentrated, artificially created electromagnetic fields that bombard us on a daily basis. It’s this human-made energy, which we deliberately produce and harness, that will be our focus.

Harmful EM Fields vs. Healing EM Fields

Not all EM fields are dangerous. In fact, many are biologically necessary. Take, for example, certain *far infrared radiation* (FIR) wavelengths, which comprise a very narrow subset of the much larger *infrared* wavelength category that produces heat. We would die without these FIR wavelengths. Readily absorbed by water, these rays promote vital life processes such as egg hatching and cell division. (This is one reason a FIR sauna can be healing, in addition to its function of helping the body sweat to excrete toxins.) Another example of beneficial EM radiation is the minuscule amounts of electrical current (*microcurrent*) produced by the human brain and nervous system, which allows various parts of the body to communicate with each other. A third example of healing EM radiation is a particularly narrow band of *ultraviolet light* (within the larger category of UV light), which acts as a disinfectant and is healing for the eyes and skin.

Detractors of legitimate research like to cite the sun as a natural EM radiation source. They correctly point out that the sun is constantly transmitting EM radiation—radio frequencies, microwaves, and other wavelengths—thus attempting to minimize the dangers of certain EM fields. However, naturally-occurring solar radiation is different from human-made electrosmog. Radiation from the sun is *diffuse*, whereas electrosmog radiation is *coherent* and *concentrated*: one must purposely create, augment, focus, and direct electrons to turn on a light bulb. We evolved under natural, diffuse solar radiation, not the unnaturally concentrated and bombarding radiation from electric lights and other electrical devices. Moreover, our daily exposure today is over a million times higher than the levels of background EM radiation under which we evolved. Put another way:

Harmful EM Fields

- ◆ Signals are chaotic, sporadic, and inconsistent.
- ◆ Frequencies are in the range of living cells; combined with the chaos of the signal, they disrupt cellular function.
- ◆ Remove electrons from the body, thus supporting the propagation of free radicals.

Healing EM Fields

- ◆ Signals are coherent, regular, and uniform.
- ◆ Frequencies may be in the range of living cells, but wave coherence makes them compatible with living organisms.
- ◆ Add more electrons to the body, thus helping to inhibit free radicals.

THE ELECTROMAGNETIC SPECTRUM

To summarize, the effects of EM radiation depend on:

- ◆ *Where on the EM spectrum* the wavelengths exist—in other words, *what type of wave* it is.
- ◆ The *concentration*—coherence vs. diffusion—of these wavelengths.
- ◆ The *voltage or force* with which these wavelengths interfere with bodily functions.
- ◆ *How* that radiation is being *transmitted and administered*.
- ◆ *Proximity* of the individual to the source of the field.

All of the above circumstances can literally make the difference between wellness and illness, life and death.

Harmful EM Fields

The Science

Starting from the high-frequency end (top) of the EM spectrum chart, there's *ionizing radiation* (which mainly consists of gamma rays and X-rays), and *non-ionizing radiation* (everything else). Ionizing radiation contains so much energy that it emits single, unbound, unstable electrons called *free radicals*. In an effort to become stable, the free radicals attach themselves to the outer rings of atoms in your body, which in turn displaces your own original electrons—and creates more free radicals in a chain reaction. Free radicals cause major tissue and DNA damage. Ionizing radiation is known to be radioactive, so its harm is generally no longer disputed.

The Politics

Deliberately perhaps, many of the published studies on harmful EM wavelengths have focused on ionizing radiation (gamma and X-rays). In many parts of the world, the dangerous, complex biological effects of non-ionizing radiation have been ignored, trivialized or denied—either due to ignorance, or (more likely) the deliberate manipulation and withholding of scientific data. Many people perceive our everyday electronics (such as cell phones) as so indispensable to our comfort, lifestyle and even survival, that they'd rather overlook the serious health problems that these fields can cause.

The Terminology

Artificially produced electricity that produces harmful EM fields can be either wireless or wired. Here, we will mostly be addressing the non-ionizing frequencies from 0.1 Hz to 300 GHz. This harmful radiation is popularly known as "EMF," short for *electromagnetic fields* (not the engineering term *electromotive force*). Even though the phrase "electromagnetic field" is technically neutral, its designation of harm has become fixed in the popular lexicon. "EMF pollution" is more precise. However, to promote greater accuracy and avoid confusion, I will use the term *electrosmog* (sometimes called *dirty electricity*).

What These Harmful EM Fields Are

Almost everything that runs on electricity emits harmful radiation. From the lowest frequencies to the highest, the wavelengths are:

- ◆ Alternating Current (AC) Electricity, in the Extremely Low Frequency (ELF) range
- ◆ AM and FM Radio Frequencies
- ◆ Television Rays, including Ultra-High Frequency (UHF) and Very High Frequency (VHF)
- ◆ Microwaves

The higher the "G" (generation) rating—1G, 2G, 3G, 4G, and most recent, 5G—the more harmful the technology.

Specific Electrosmog Wavelengths

Extremely Low Frequencies (ELF) in the Alternating Current Electricity Range

How It's Produced. Basic electrical current—the kind we use in our everyday lives—can be produced in two different ways, and they don't affect the body in exactly the same ways.

Thomas Edison, inventor of the incandescent light bulb, developed *direct current* (DC). With DC, there's a steady flow of electrons (current) in one direction. However, Edison found that the current couldn't travel very far without dissipating. This made it necessary to build massive converter boxes at regular locations to increase the force of the flow and propel the electrons forward. Hence, DC was both impractical and costly.

In response to the difficulties of DC, Edison's rival Nikola Tesla (well known for his "free energy" inventions and use of electricity in novel ways) developed *alternating current* (AC). AC electricity travels long distances. To do this, each electron travels a short distance, bumps adjacent electrons, and then returns to its original position. In turn, the adjacent electrons bump electrons next to *them*, return to their original position, and so on. This constant bumping of electrons causes a flow of current through a wire. However, because the direction of the electron flow reverses repeatedly, every time the electrons change direction the field collapses and reappears. The overall charge changes from negative (signifying the presence of electrons) to positive (due to the relative absence of electrons). This back-and-forth direction of electrons disrupts the biological processes in a living body. Also, whereas DC creates a steady magnetic field, AC creates a fluctuating magnetic field, of varying strength, each time the electrons reverse direction—which is likewise disruptive. You might analogize DC as a gentle, steady, continuous stream of water, while AC is the relentless, irregular crash of ocean waves pushing and pulling. DC is gentle to living systems, while AC is destructive.

Biological Effects of AC. Touching the wires or being in the field of any electrical current (DC or AC) can maim or kill you if the power is too high. However, AC is dangerous in another way, at lower power levels that we routinely use. The extremely low frequencies (ELF) in electrical sockets and wiring range from 0.01 Hz to 300 Hz. These are the same ranges in which human tissue oscillates. For example: signals from a low-frequency WiFi pulse are in the same range as signals used by the brain and nervous system, so the brain tries to lock on to WiFi signals and becomes confused. Also, the body of a human (or animal) resonates with, or becomes *entrained* to, the fields to which it's exposed. Thus, when people touch or are near an electrical appliance operating at 60 Hz (in North America) or 50 Hz (in most of the world), that same field is generated in us. Furthermore, electrons flowing through a wire produce magnetic fields, which cause even more problems than electrical current because they affect the iron in the blood and elsewhere, destroying cell membranes and interfering with our electrolytes. Electrosmog crosses the blood-brain barrier, so there's no natural protection in our brains against its effects. And it changes the rotation and spin of electrons in our bodies, altering the chemical bonds of molecules and causing breaks in our very DNA.

This literal change in our DNA has far-reaching repercussions. The nervous system can't process signals properly. Hormone production, calcium exchange and tissue growth are skewed. The pineal gland (which is sensitive to even minute changes in electromagnetic fields) reduces the amount of the hormone melatonin that it synthesizes and secretes. Melatonin is not only required for restorative sleep, but it also helps regulate growth and the cycles of other hormones. And it supports immune function and inhibits the growth of tumors. A melatonin deficiency diminishes one's ability to learn, and is even responsible for depressive states along with sleep disorders and fatigue. The effects of electrosmog on the pineal gland alone account for health problems almost too numerous to count.

It's easy to see why ELF is so dangerous. *Electrical devices overpower the body's natural electromagnetic oscillations, forcing us to resonate in ways that prevent our biological processes from optimally functioning.*

The Swiss Agency for the Environment, Forests and Landscape (SAEFL) acknowledges that certain biological effects occur at exposure levels well below internationally recommended limits—and that as a result, it's wise to take precautions to protect oneself from the damage caused by ELF radiation. Most people don't know that even an electrical socket, with nothing plugged into it, carries "live" electricity that can cause destructive biological effects—particularly if the socket is next to the body for a long time (as in a socket at the head of a bed, where you sleep for the entire night).

Radio Frequencies (RF) and Wireless (WiFi)

Higher up on the EM spectrum are radio frequencies or RF. As with the lower EM bands, radio frequency wavelengths contain both electric fields and magnetic fields. For many years, scientists have known that high levels of RF radiation are harmful because RF can rapidly heat biological tissue (the principle by which microwave ovens cook food), and the body is unable to dissipate the excessive heat. This is especially true of areas such as the eyes and testes that lack substantial blood flow.

Scientists refer to the damage caused by heating from RF as *thermal* (temperature-related) effects. While technically correct, this phrase is misleading because it can imply that if tissue's not heated, there's no damage. But radiation produce significant, sometimes lethal *nonthermal* damage—common with wireless technology or WiFi, which broadcasts in ultra-high frequency bands.

Wireless technology includes internet routers, modems, mobile phones, Bluetooth, cell phones and their towers. WiFi damages the heart as well as the nervous system, which means a higher incidence of heart attacks and neurological disorders including concentration and cognition difficulties. Cell phone radiation causes DNA damage, resulting in inflammatory conditions, infertility, heart disease, and cancer. Brain tumors typically appear on the side of the head favored during cell phone conversations. A phone in a breast pocket increases the chances of breast cancer and heart problems; in a side pocket near the groin area, cell phones promote infertility. WiFi against the body causes a rapid deterioration of health; but even WiFi near a person causes considerable damage. It's even making bees desert their hives. And the newer proposed "5G" WiFi is just as dangerous. Resonating in the frequency of sweat glands, it prevents people from perspiring.

Sensitivity To Electrosmog Escalates

Sensitivity to electrosmog is known as *electrosensitivity*. People who are bothered by electrosmog are known as *electrosensitive*. Electrosmog damage is exponential. Repeated, unremitting exposure exacerbates any underlying weakness and causes new health problems to arise, including degenerative conditions and increased susceptibility to infectious diseases. The dangers of electrosmog been known since even before the 1960s.

A good health practitioner investigates a client's environment. This includes exposure to not only chemicals, but also to electrical and magnetic fields. People may need to rewire their house or unplug appliances (particularly those near their bed)—or even move to a different home entirely to avoid nearby cell towers and major power lines. There are many reports of both humans and their pets developing similar conditions, including cancer. Once the electrosmog is eliminated, the people and animals become well.

Health Problems Worsened or Outright Caused by Electrosmog

- ◆ Allergies of all types
- ◆ Arthritis, including rheumatoid arthritis
- ◆ Autoimmune disorders, including Multiple Sclerosis and lupus
- ◆ Birth defects, genetic abnormalities, infertility, miscarriage, problem pregnancies, stillborn births
- ◆ Blood sugar problems, including “brittle” diabetes
- ◆ Cancers, including brain tumors and leukemia
- ◆ Cardiovascular problems: increased incidences of heart attacks, chest pain, erratic pulse, high blood pressure
- ◆ Digestive disturbances, including poor absorption of food, leaky gut, nausea, and vomiting
- ◆ Emotional distress, including excessive anxiety, irritability, mood changes and panic attacks, along with a higher-than-average suicide rate
- ◆ Ear problems, including noise sensitivity and tinnitus
- ◆ Eyestrain, deteriorating vision, cataracts
- ◆ Fatigue, excessive and unremitting
- ◆ Fibromyalgia, chronic pain, excessive inflammation
- ◆ Headaches and migraines
- ◆ Hormonal abnormalities of all kinds
- ◆ Immune malfunction, resulting in abnormally high levels of infections and inflammation
- ◆ Insomnia and other sleep disturbances
- ◆ Infections, all, increased or exacerbated (pathogens go into “alarm” mode when exposed to electrosmog)
- ◆ Nervous system disorders: confusion, convulsions, dizziness, hyperactivity, memory loss (including Parkinson’s and Alzheimer’s), seizures
- ◆ Respiratory issues, including asthma
- ◆ Skin disorders: burning, tingling, rashes, pain
- ◆ Stress increase and intolerance, in part due to adrenal gland impairment

Contributors to Electrosmog Sensitivity

- ◆ Electrosmog exposure that’s cumulative, over a long period of time
- ◆ Electrosmog exposure at dramatically high levels (either a single exposure, or several exposures)
- ◆ Health issues that are pre-existing
- ◆ Heavy metal toxicity
- ◆ Immune impairment
- ◆ Iodine deficiency
- ◆ Lyme disease, and any other illness (such as cancer) that has substantially impaired immune function
- ◆ Stress—either high levels, or repeated (how much stress, and what kind, depends on the individual)

Common Electrical Items that Produce Electrosmog

- ◆ Air conditioner
- ◆ Airport scanner (well known to emit dangerous ionizing radiation from high-intensity X-rays)
- ◆ Chargers for cell phones, laptops, tablets, etc.
- ◆ Clock, clock radio
- ◆ Clothes dryer
- ◆ Computer, monitor, printer, scanner, photocopier
- ◆ C-PAP machine (used for sleep apnea)
- ◆ DVD or Blu-Ray player, amplifier
- ◆ Electric blanket, water bed
- ◆ Fan (on floor or ceiling, and in computers)
- ◆ Hair dryer, curling iron
- ◆ Heater (portable)
- ◆ Hot plate
- ◆ iPad, iPod, Android, Kindle, any portable reader
- ◆ Iron (for clothing)
- ◆ Kitchen appliances: blender, dishwasher, food processor, mixer, electric oven/range, refrigerator, toaster, microwave oven (in the Gigahertz range)
- ◆ Light bulb, especially compact fluorescent (emits RF and UV, and contains mercury)
- ◆ Phones: cell, cordless, bluetooth, answering machine (corded is safer; it doesn’t constantly transmit signal)
- ◆ Power tools: drill, saw, electric screwdriver
- ◆ Shaver (electric razor)
- ◆ Smart meter (allegedly installed to regulate electrical usage, it’s highly dangerous and inaccurate)
- ◆ Television and radio transmitter
- ◆ Stereo equipment and amplifier
- ◆ Vacuum cleaner
- ◆ Washing machine
- ◆ ...living near a cell tower, high-voltage power line, transformer station, railway, or radar installation

What To Do About Electrosmog (Dirty Electricity)

Make Sure Your Electrical Wiring and Outlets Have Been Properly Designed and Installed

Faulty wiring causes intense stray magnetic fields. These magnetic fields often appear in homes that have been built on a budget (and quickly), and in buildings erected before the 1960s, which used crude wiring methods. Magnetic fields result from a lack of shielding, improper grounding, or both.

Shielding refers to the various ways in which electrical wiring is physically covered with various materials, or configured so that stray magnetic fields are eliminated. *Grounding* means that the excess charge (electrons) from wiring are returned to the ground or soil (Earth), thereby eliminating the possibility of short-circuiting or harming a living body with stray current.

A *gauss meter* measures magnetic fields. A meter measuring only field strength costs under two hundred dollars; more expensive ones detect the frequencies as well. An *outlet tester* shows whether that socket is properly grounded, and costs less than ten dollars.

If you live in an old house or sense that your illness could be due to electrosmog, call a licensed electrician who can inspect and clear your environment.

Avoid Close Proximity

Electrosmog is significantly higher in equipment that emits strong magnetic fields. This includes appliances that generate lots of heat (broilers, hair dryers, hot plates), that contain magnetic coils or transformers (TVs, low-voltage halogen and fluorescent lamps, clock radios), or are equipped with electric motors (drills, blenders, vacuum cleaners). Limit the time you spend with them. Note that as the distance from the source of a magnetic field increases, the intensity of the field exponentially decreases. So, depending on the item, keep it between one foot (about 30 centimeters) and three feet (60 or 90 centimeters) away. Magnetic fields penetrate solid objects, so be aware of what's on the other side of a wall, especially the wall at your bed.

- ◆ Turn off or unplug surge protectors and equipment that you're not using. Even when off, appliances consume electricity and still produce magnetic and electric fields. Install a *demand switch* to automatically turn off unused electrical currents.
- ◆ You can't avoid wireless from public facilities or neighbors, but you *can* control your home. Don't use wireless Internet! (Wired Internet is faster anyway.)
- ◆ Use your cell phone on speaker or with a wired (not Bluetooth) headset. *When not using it, turn it off.*
- ◆ Don't put a laptop, tablet or cell phone on your body.
- ◆ Engines on trains, cars and planes produce strong magnetic fields. An enclosed metal structure can intensify electrosmog. See next column.

Equipment and Tools to Shield, Protect and Normalize

The new 5G wireless technology resonates in the wavelength of our sweat glands—which are like antennas for 5G—and can thus interfere with our ability to sweat. Even if you don't own a cell phone, you'll absorb the radiation simply by being near a 5G cell tower. Few people will be able to avoid sources of electrosmog, so protective tools seem mandatory.

Products either *shield* or *block* radiation, or *harmonize* or *neutralize* the radiation so that it no longer causes problems. Some of the products are placed around or on an electrosmog-emitting appliance (cell phone, computer, etc.), while others are worn or placed on the body. A few items run on electricity; most do not. The protective ability of some products is shown with "before" and "after" photos of live blood taken through a darkfield microscope. While exposure to a cell phone will produce abnormally flattened, clumped red blood cells (indicating low voltage and oxygen levels), photos after exposure to an EMF protector/neutralizer will show normal separate, round blood cells (indicating higher voltage and oxygenation). Other tests include Kirlian photography, Gas Discharge Visualization (GDV), and of course whether one's health improves.

Make sure the product doesn't absorb harmful radiation. If you don't know when to clear it, you could absorb electrosmog from the very tool you're relying on to protect you. Below, a small sample of EMF protectors.

Items that Shield. Some materials block stray magnetic and electric fields. These include rare earth, a mineral; Mu metal, an alloy used to shield electronic components; and fabrics and paints imbued with materials that reflect or ground radiation. See lessemf.com.

Items that Harmonize or Neutralize. Jewelry, decals, and pocket-size items made of stone, metal or ceramic can be imbued with frequencies; and some liquids and solid materials (especially in crystalline form) can be imprinted. Some tools passively emit an energy field that transforms the chaotic electrosmog into more organized, gentler wavelengths. Others directly strengthen one's energy field and help the body withstand the harm from electrosmog. Some products that may help are made by Aulterra, Earthcalm, Energyintegrity, Eradicator Technologies, and Tuning Element (see Appendix A).

The Pulsed Technologies electronic VitaSet Generator emits all of the Schumann Resonances, including the best-known 7.83 Hz. Humans originally evolved and resonated to these frequencies (see Chapter 5). According to Dr. Patrick Flanagan, iron oxide powder (sold as jewelers rouge) emits 7.83 Hz when exposed to an EM pulse. Three tablespoons mixed in a gallon of paint or glue, and applied in small amounts to a cell phone, computer, light or appliance, will focus the body on this restorative resonance instead of electrosmog.

Noise Pollution

Noise pollution is any unwanted, disturbing sound that interferes with the ability to sleep, converse, or hear. Until relatively recently in Earth's history, the concept of noise pollution didn't even exist because there were very few causes of constant, excessive noise. But today, outside, there's construction, road traffic, and aircraft. Indoors, in the average home, any appliance—including, but not limited to, a hair dryer, refrigerator, vacuum cleaner, coffee grinder, washer, dryer, radio, television or power tool—adds to the ambient noise level (not to mention the harmful EM fields emitted by these electric devices).

In order for a sound to be regarded as noise pollution, it must be either frequent or constant, as well as loud—usually above 55 decibels (dB). (A *decibel* is a measurement of loudness. The human ear subjectively perceives a sound as twice as loud when the volume increases by 10 dB.) Noise over 80 dB can cause ringing and pressure in the ears and hearing distortions, with eventual hearing loss. At 110 dB, noise can cause pain; and at 135 dB, permanent deafness. The physiological component to abnormally loud and relentless noise is the damage of the delicate hair cells in the inner ear, cells that are replaced with scar tissue.

Aside from damage to the ear, the stress from noise pollution causes problems ranging from stroke, high blood pressure and heart attacks to nerve conditions (including epilepsy and loss of balance) to gastrointestinal distress such as ulcers. Emotional agitation may be so intense, it leads to suicide. In 2011, it's estimated, 20% of North Americans over 12 years of age suffered from hearing loss.

Interestingly, after repeated exposure to high noise levels, people often still “hear” the offending sound, even long after the noise has stopped.

Injury

The relationship between injury and infection is complex but easy to recognize, once you understand how injury can lead to illness.

Inflammation is the body's way of dealing with irritation—whether the irritation is caused by pathogens (infection), chemicals, physical trauma, heat, or toxins. During inflammation, various scavenger cells gather at the problem site to ingest dead and damaged tissue. The scavenger cells also act as a cushion or barrier between the local damaged cells and the surrounding healthy tissue. In addition, blood supply increases to bring extra nutrients, oxygen, and hormones to the repair site. *Infection*, on the other hand, is a pathological, diseased state of the tissues involving harmful microbes. They force their way into our cells and introduce waste that doesn't belong: the byproducts of their own metabolic and survival

functions. *This is the point at which inflammation due to injury can cause infection.* If scavenger cells cannot digest injured tissue quickly enough, the damaged cells will putrefy. Then, pathogens proliferate in the area because they have an excellent food source—you. Now, the body's inflammatory response is no longer useful but harmful, as circulation is further impaired and even more swelling occurs. (At this point, to eliminate the swelling, alternating heat and cold are applied, via water, hot and cold packs, and even a sauna and plunge into a cold pool.)

Any debris of any origin that remains in the system without being eliminated, can cause inflammation and eventually infection. Sudden physical shock that causes tissue damage can aggravate already existing problems and bring pathogens to an area where previously there were few or none. This is why an accidental injury can cause long-term or even permanent harm. What began as a mechanical stress becomes a biochemical issue.

Inflammation

There's an inflammatory response, often independent of injury, that scientists now recognize as responsible for not only infections, but virtually all degenerative conditions (including autoimmune disorders, insulin resistance and arthritis). This inflammatory response is caused by a group of tiny proteins called *cytokines*. Among their other functions, cytokines instruct different types of immune cells to fight infection; and in turn, the immune cells produce more cytokines until the job is complete. However, due to stress (with its high cortisol levels) and other factors, an overproduction or malfunction of cytokines, called a *cytokine storm*, develops. These cytokines deliver faulty messages to the immune cells, which produce yet more cytokines. Due to this feedback loop that the body cannot halt, massive inflammation develops. In turn, the inflammation can cause infection.

Ironically, chronic infection can also cause cytokine storms, which leads to inflammation and yet more infection. A highly pathogenic invader, or other unusual assault on the immune response (such as toxic metals), can trigger a cytokine storm.

Inflammation corresponds to high oxidative stress, reduced blood flow, and acidic pH. See below.

pH Imbalance

A major contributor to illness is a disturbance in pH, or levels of acidity and alkalinity in the body's various fluids and tissues. (Popular usage states that pH means “power of hydrogen” or “potential of hydrogen,” but the term is actually derived from “p,” a mathematical symbol

According to conventional medicine, when the blood pH is over 7.45, it's too alkaline. However, Dutchman Wim Hof has measured significantly higher (alkaline) blood levels, sometimes up to 7.75. He teaches a breathing technique that increases the capacity of red blood cells to carry oxygen for extended periods, thus lowering systemic carbon dioxide levels and raising oxygen levels. As a result, he and his students who practice this protocol enjoy greater immunity, more energy, improved tissue function, and an augmented sense of well-being. Evidently, a new model for optimal blood pH—if not overall health—is needed.

used to make the negative logarithm calculation, and “H,” the chemical symbol for hydrogen.) Technically, as a measurement, *pH* denotes the concentration of hydrogen ions in a water-based solution. (An *ion* is a charged particle that has gained or lost one or more electrons.) *When ions are present in a liquid, electrical energy can be conducted through the solution.* In a liquid, different elements form ions in varying amounts, depending on the ability of the atoms to gain or lose electrons. These atoms dissociate (ionize) in solution to form hydrogen ions (H⁺) or hydroxyl ions (OH⁻). Even though pH selectively measures only hydrogen ion activity, it refers to both acidity and alkalinity because the lessening or absence of H⁺ implies an increase or the sole presence of OH⁻.

Why is this dry bit of chemistry relevant? The minerals dissolved in solution not only determine the presence of hydrogen ions and hydroxyl ions, but they also act just like batteries and *conduct an electrical charge*. This allows nutrients to enter the cell and wastes to leave. If the electrical charge of the cells and bodily fluids is too weak, our bodies don't work properly and we become ill.

Depending on the presence or absence of H⁺ and OH⁻ ions, the solution will be acidic, neutral or alkaline. If the H⁺ concentration is greater than OH⁻, the material is acidic. The concentration of hydrogen ions is measured on a scale of 0 to 14. The pH values of acids range from 0.0 to 6.9 (less than 7.0). If the OH⁻ concentration is greater than H⁺, the material is alkaline or basic. The pH values of bases range from 7.1 to 14.0 (greater than 7.0). If equal amounts of H⁺ and OH⁻ ions are present, the material is neutral, at exactly 7.0. Note that the numbers on the acidity/alkalinity scale do not represent equal divisions. Each number higher than the one before it represents an exponential increase: 1 is ten times greater than 0; 2 is ten times greater than 1 or one hundred times greater than 0; 3 is ten times greater than 2 or one thousand times greater than 0, and so on. This means that even a small change in the measurement of acidity matters a great deal.

There's a popular conception in health-conscious circles that one must have an “alkaline” system. However, this notion is simplistic and inaccurate. Some areas of the body need to be acidic and other areas, alkaline. Normal skin has natural surface acids that form a protective barrier. Saliva must be alkaline because it digests starches (carbohydrate digestion begins in the mouth). And the stomach's hydrochloric acid must remain at about a 2.0 pH, which is very acidic. Hydrochloric acid helps the inactive form of pepsin convert to its active form, and thus digest animal and vegetable proteins.

The body's tissue pH and its fluid pH are related. Salivary pH indirectly reflects the pH inside a cell membrane, while urinary pH reflects the extracellular fluid. When cells detoxify, the extracellular pH rises (allowing cells to dump more toxins), and urinary pH falls (reflecting this housecleaning). If some regions become excessively alkaline, other areas become excessively acidic in response. This is why testing only urine, or only saliva, provides an incomplete biochemical portrait. Also, there's an inverse relationship between acidity in the stomach and acidity in the body. The more desirably acidic the stomach is, the more desirably alkaline the body tissues are; and the more undesirably alkaline the stomach is, the more undesirably acidic certain parts of the body are. (Sufficient hydrochloric acid in the stomach means that no undigested food particles will leak through the intestinal wall to lodge in cells as irritating, usually acidic wastes.)

Conventional medicine tells us that the one body area whose pH *must* stay within a very narrow range of alkalinity is the arterial blood plasma. (The watery blood plasma is a liquid—entirely separate from the round red blood cells that float in it, and whose iron content gives the blood its red color.) With a sub-optimal pH, the red blood cells don't release enough oxygen to the tissues. The ideal pH for blood plasma is typically cited as not less than 7.35 and not more than 7.4 or 7.45 (the upper limit), depending on what source you read. If the blood deviates too much from its ideal pH for too long, the person becomes sick and dies.

The job of *regulating* the acid-alkaline levels belongs to the respiratory tract, the chemical and physiological buffering system (which includes the liver), and the urinary tract. The respiratory tract alters the rate of carbon dioxide ventilation from the bodily fluids. This in turn changes the ion concentration through a series of biochemical processes. The chemical and physiological buffering system of the body undergoes a number of different steps to produce special biochemicals that also counteract the acidic pH imbalance in the blood plasma.

It's the urinary tract (the kidneys in particular) that most efficiently *eliminates* acids. However, this method

has its limitations. No matter how hard the kidneys are forced to work (assuming they don't become overloaded), there's only so much acidity they can eliminate. The blood transports excess acid to the kidneys only a little bit at a time, and slowly. After the kidneys have excreted all they can, if excess corrosive acids and acid-forming substances still threaten to damage the bloodstream, the acids are simply relocated elsewhere in the body to protect the blood. These toxins get stored in the extracellular fluids (fluids surrounding the cells), the connective tissue, the joints, and even the organs.

Metabolic wastes accumulate in the system more easily than people realize, which is how a chain reaction of deterioration in bodily functions starts to occur. Autointoxication—being poisoned by one's own toxic wastes—lays the foundation for degenerative conditions including arthritis and bone loss, allergies, cardiovascular problems, diabetes, fibromyalgia, kidney stones, and even cancer. This is why cleansing and detoxification are so central to natural medicine.

Storing overly acid or alkaline wastes in the tissues to get them out of the bloodstream—while a necessary and viable intervention by the body—is, at best, an emergency, short-term solution to a pH imbalance. Bone loss is a good example of a highly unbalanced, overly acidic system. It also graphically illustrates a malabsorption or shortage of calcium and other minerals, which are key factors in maintaining the proper pH. Most of the calcium we ingest is not used for bone construction, but instead freely circulates in the body to be utilized in various metabolic processes, including the neutralization of systemic acids. The blood's pH balance is so crucial that when no more calcium is available, the body leaches it from the bones. This is why getting sufficient calcium is so important. However, the calcium must be balanced with other nutrients, including Vitamin K2, magnesium and boron, which help the body absorb and utilize the calcium. Otherwise, bone loss and other symptoms commonly associated with calcium deficiency occur, due to the excess calcium that's disintegrating the bones. Note that there are acid-forming and alkaline-forming varieties of calcium, and different people require different forms.

As I hope you're beginning to see, testing for pH, interpreting the results, and correcting imbalances isn't simple! Although a disturbed pH can be due to many factors, the converse is also true: a pH imbalance can augment already existing conditions or even cause new ones. Sometimes a seriously ill person can become well just by correcting the pH. Please consult a practitioner who understands body chemistry and your unique nutritional needs. Whatever the issue, though, eating lots of greens or drinking chlorophyll in water can help everyone.

Proliferating Pathogens

Harmful microorganisms are an obvious component of illness. The same unbalanced pH that contributes to tissue deterioration also allows bacteria, viruses, parasites and fungi to grow. The speed of pathogen proliferation also depends on glucose and oxygen levels. Harmful microbes love sugar and most thrive in a low-oxygen environment.

In the body, pathogens steal nutrients from the foods you eat. They also excrete waste. Wastes from fungi, called *mycotoxins*, are particularly nasty. (*Myco* is from the Greek word *mykes*, which means “fungus.”)

The corpses of these microorganisms can also toxify. Sometimes a leukocyte (white blood immune cell) attacks, immobilizes and devours a pathogen whole. However, this scenario is not always possible. In many people who are ill—particularly if they have chronic conditions—the immune cells are not plentiful enough, or functioning well enough, to scavenge the invaders whole. Instead, a portion of the pathogen breaks apart, spewing its toxic waste into the bloodstream. (Many of these microorganisms, when threatened or dying, leak toxins from their walls to defend against a counterattack by the host.) A pathogen may also rupture, rather than simply become immobilized, due to drugs or anti-microbial herbs in the system, or electromedicine protocols (such as Rife Therapy) that use beneficial frequencies to devitalize microorganisms.

Most people haven't heard of the mycotoxin called *acetaldehyde*, which is excreted by *Candida albicans*. They are, however, familiar with acetaldehyde's *breakdown* products, which are also found in many foods: oxalic acid, uric acid, and alcohol.

Oxalic acid is a common food toxin, present in large amounts in tomatoes. If foods containing oxalic acid are eaten by a susceptible person continually, in large enough quantities—as in the concentrated form of tomato sauce—oxalic acid can cause inflammation in the joints.

Uric acid cannot be destroyed by the body. If the acid isn't excreted by the kidneys, it crystallizes as kidney stones.

As for alcohol, reframing this legal drug as a toxin offers a different perspective from how it's ordinarily viewed. Alcoholic beverages are produced when a fruit or grain is allowed to ferment. During the fermentation process (which by definition takes place in the absence of oxygen), the yeast feeds on the food sugars and excretes the desired alcohol. But alcohol is actually a waste product—yeast poop! Its rapid metabolism by the body can cause liver damage. And alcohol interrupts the transmission of signals across neurons, which people experience as intoxication and for the most part consider enjoyable.

The foul waste from pathogens is commonly known as *die-off*. As sick people know, die-off feels terrible. The more noxious the waste is that's discharged into the body, the more ill we feel. The body reacts to this assault by registering pain (the nerves are being irritated by toxins), by malfunctioning (microbial toxins further disrupt the body's pH and impede waste removal), or by swelling (to contain the infection). Chapters 3 and 4 address how to deal with this waste.

Toxic Bodily Responses

Illness can result from noxious biochemicals, hormones, or other *endogenous* substances—*produced by the body itself*—in response to microbial or any other toxins.

One example is a *cyst*, or a sac that contains liquid. Cysts form around foreign material in the body to contain it and prevent the rest of the system from being poisoned. Conventional doctors often perceive a cyst as the medical condition itself rather than as an expression of a deeper malfunction. In their paradigm, the cyst is the cause of a problem rather than the effect. The body's attempts to protect itself, while not always convenient or efficient, do demonstrate an effort to achieve equilibrium. The holistic model recognizes that the body's formation of cysts is related to an impaired waste removal function.

Another example of a toxic bodily response is deranged macrophage activity. Primarily located in the bloodstream and connective tissue, a *macrophage* is a type of white blood cell that recognizes, engulfs and destroys pathogens, the body's own dead cells, and other microscopic debris. However, the immune function of these cells can fail if the body signals too much inflammation. When there's an overabundance of inflammatory cytokines, macrophages (and other cells) release the protein-digesting enzyme *protease* into the tissues, causing severe damage. Once the body's tissues are damaged, the cells leak magnesium and potassium, allowing an influx of water and sodium. This causes a reduction of cellular charge (electrons), with a concurrent oxygen shortage. In the absence of oxygen, the cells must now burn fuel in a different, less efficient way. This inefficient burning of fuel now produces *lactic acid*, a byproduct of *anaerobic* (oxygen-deprived) metabolism. To protect themselves from this excess acid, the cells dump it into the extracellular fluids. The acidic waste buildup, in turn, leads to pathogen proliferation and even cancer.

One more example. In people of normal weight, the macrophages in fat heal wounds. In obese people, the macrophages promote inflammation and insulin resistance.

Toxic bodily responses are always related to illness.

Lack of Exercise and Movement

Exercise is now part of every holistic and conventional health program. Sitting at desks daily, for hours at a time, is not part of our evolutionary development. We were naturally made to move. Even gentle walking pumps the lymph tissue, makes our hearts stronger, and helps the body create its own endorphins, those biochemicals that elevate mood and stem inflammation. See Chapter 3, **Exercise**, for more information.

Emotions and Belief Systems

The final, but very important, component to becoming ill is one's emotional state and belief systems.

Emotional states include joy, anger, love, rage, sadness, and excitement. "E-motion" is *energy in motion*, which corresponds to the body's electrical and chemical messengers. Electrical messengers are the charge that energizes the nervous system. Chemical messengers are the minute amounts of hormones that circulate throughout the bloodstream. For instance, fear and depression occur simultaneously with the outpouring of the fight-or-flight corticosteroid adrenal hormones.

A feeling can be divided into two parts: the emotional content, and the urge to express the emotion through action. For instance, love (the emotion) is a tangible energy or charge. It builds up, expanding the heart and chest cavity in a pleasurable way. When the energy substantially accumulates, people feel a need to discharge that energy. This is often done through a hug or other affectionate touch (the act), which allows the built-up energy to flow out from the chest through the shoulders, arms and hands. Sadness (the emotion) is accompanied by crying and sobbing (the act) to discharge the energy, and so on.

Holding back from expressing an emotion generally begins as a conscious behavior, and people are aware of their choice. But over time, if the emotional issue is not resolved, this holding back becomes unconscious or automatic, beneath one's level of awareness. At one time or another, most of us have probably held our breath when faced with dread, fear, or other uncomfortable emotions. More chronic, habituated responses to avoid feeling deeply include shallow breathing (which inhibits the natural biological response or *act* of vocalizing those emotions) and biting the lower lip and tensing the abdominal muscles and diaphragm (to prevent sobbing). Once the reason for holding back is not addressed, the muscular contraction that initially was deliberate becomes automatic, so the person is no longer aware of the emotion being held in the tensed muscles.

Bruce Lipton, PhD on Epigenetics: Your DNA Is Not Your Destiny

Medicine does miracles, but it's limited to trauma. The AMA protocol is to regard our physical body like a machine, in the same way that an auto mechanic regards a car. When the parts break, you replace them—a transplant, synthetic joints, and so on. . . .

The problem is . . . while they have an understanding that the mechanism isn't working, they're blaming the vehicle for what went wrong. They believe that the vehicle, in this case our bodies, is controlled by genes.

But guess what? They don't take into consideration that there's actually a driver in that car. The new science, epigenetics, reveals that the vehicles—or the genes—aren't responsible for the breakdown. It's the driver.

Conventional medicine is operating from an archaic view that we're controlled by genes, [misunderstanding] . . . the nature of how biology works. . . . [But] our health is not controlled by genetics. . . . Epigenetics [is] the study of inherited changes in phenotype (appearance) or gene expression caused by mechanisms other than changes in the underlying DNA sequence. . . .

It used to be that we thought a mutant gene caused cancer, but with epigenetics, all of that has changed. I placed one stem cell into a culture dish, and it divided every ten hours. After two weeks, there were thousands of cells in the dish, and they were all genetically identical, having been derived from the same parent cell. I divided the cell population and inoculated them in three different culture dishes. Next, I manipulated the culture medium—the cell's equivalent of the environment—in each dish. In one dish, the cells became bone, in another, muscle, and in the last dish, fat. This demonstrated that the genes didn't determine the fate of the cells because they all had the exact same genes. The environment determined the fate of the cells, not the genetic pattern. So if cells are in a healthy environment, they are healthy. If they're in an unhealthy environment, they get sick.

With fifty trillion cells in your body, the human body is the equivalent of a skin-covered petri dish. Moving your body from one environment to another alters the composition of the "culture medium," the blood. The chemistry of the body's culture medium determines the nature of the cell's environment within you. The blood's chemistry is largely impacted by the chemicals emitted from your brain. Brain chemistry adjusts the composition of the blood based upon your perceptions of life. So this means that your perception of any given thing, at any given moment, can influence the brain chemistry, which, in turn, affects the environment where your cells reside and controls their fate. In other words, your thoughts and perceptions have a direct and overwhelmingly significant effect on cells.

The function of the mind is to create coherence between our beliefs and the reality we experience. What that means is that your mind will adjust the body's biology and behavior to fit with your beliefs. If you've been told you'll die in six months and your mind believes

it, you most likely will die in six months. That's called the nocebo effect, the result of a negative thought, which is the opposite of the placebo effect, where healing is mediated by a positive thought. . . .

People are aware of their conscious beliefs and behaviors, but not of subconscious beliefs and behaviors. Most people don't even acknowledge that their subconscious mind is at play, when the fact is that the subconscious mind is a million times more powerful than the conscious mind and that we operate 95 to 99 percent of our lives from subconscious programs.

Your subconscious beliefs are working either for you or against you, but the truth is that you are not controlling your life, because your subconscious mind supersedes all conscious control. So when you are trying to heal from a conscious level—citing affirmations and telling yourself you're healthy—there may be an invisible subconscious program that's sabotaging you. . . .

Once you become aware of the fact that invisible programs from the subconscious mind are running your life, then you are responsible for it. Becoming aware means accessing the behavioral programs in your unconscious mind so that you can change the underlying limiting or self-sabotaging thoughts that don't serve you. It's easy to figure out the nature of your subconscious programs. Just take a look at the character of your life. It's a printout of your subconscious programs. The things you're having trouble with are because of that programming.

You can rewire yourself. . . . If a disease such as cancer has progressed to an advanced stage, then you might do a round or two of chemo, but at the same time you need to be reprogramming your mind and recognizing your involvement in the disease. You must recognize that you are a participant in the unfolding of your life. Then you can go into your subconscious program and find out where the problems are. . . . Through processes such as hypnosis, subliminal tapes, the religious use of affirmations, Buddhist mindfulness, or a series of reprogramming modalities collectively referred to as energy psychology, such as PSYCH-K®, Emotional Self-Management (ESM), Eye Movement Desensitization and Reprocessing (EMDR), and Emotional Freedom Techniques (EFT)™, among many other new techniques, we can rewrite those destructive programs that occupy our subconscious field.

The amount of money you have invested in a belief system ("Doctors have the authority; I am ruled by my genes; drugs are the only cure") determines how willing you are to change it. . . . Medical institutions are operating on fear. The funding and regulatory elements know that within each of us is the power to heal.

Awareness of emotions means the ability to choose to act on them, or not act on them while having the option to release or transmute them. But being unaware of emotions extracts a price: the chronic tightening of muscles (including the diaphragm), organs, glands and even skeletal tissue. This constriction prevents nutrients as well as oxygen from reaching the tissues, which contributes to the accumulation of waste products and an unbalanced pH.

The suppression and mismanagement of emotions also contribute to illness because tension, upset and worry—which corresponds to the adrenal secretion of fight-or-flight biochemical messengers—create excess acidity in the system. In this unnatural, overly acidic condition, pathogenic microbes proliferate.

Emotions and beliefs are not the same, although they are related to each other. Belief systems are our thoughts about how the world operates (which we call “reality”). Belief systems are based on what we have been taught, and what we probably experienced. For example, someone with loving parents who helped her feel secure and wanted would be likely as an adult to view the world as a safe place, where her needs are easily met. But someone whose parents wanted her to conform to their own standards rather than accepting her for who she really was, might later view the world as a place of conflict and struggle. To these two people, the world is a radically different place.

We can influence our health by changing our physical environment, which can positively affect our emotional states. Conversely, we can change our belief systems and emotional states, which can positively affect the condition of the body. People whose illnesses are caused or strongly influenced by emotional states would benefit from some form of psychological healing that focuses on the emotions. Unfortunately, the role that emotional factors play in our health is sometimes distorted and derided by both doctors and laypersons, who use the pejorative term *psychosomatic illness*. This implies that because the diseased state is “all in one’s mind” it’s somehow not real, and thus not worth considering. But *psychosomatic* simply refers to the connection between mind and body. The emotional and mental components of illness are as important as the physical. Sometimes, simple love is the ingredient that’s missing in our lives. The restoration of love—and hence the sense of connection to oneself and others—is an essential component of healing.

At the very least, maintaining a genuinely positive outlook will enhance the quality of your life. At most, positive emotions could save your life. See Chapter 6 for revolutionary experiments in this arena.

PRESCRIPTION PHARMACEUTICALS

How Drugs Work

Drugs are designed to accomplish one of three goals (which can overlap). They numb the body so symptoms are not felt. They substitute for a bodily function. Or they substitute for a substance that the body produces. For example, painkillers are taken for a migraine, antibiotics are taken when the immune cells are too overwhelmed to handle a huge increase of bacteria, and insulin is taken when the pancreas cannot produce enough of its own.

Drugs are not usually accompanied by therapies designed to correct the imbalance for which the drugs were prescribed in the first place. However, if the *reason* for the deficiency or malfunction is not addressed, the drug may end up harming the person in ways that are worse than the disease. The longer the drug is taken, the greater the possibility of harm. For instance:

- ◆ Every drug has so-called side effects.
- ◆ The person may become so resistant to the action of a drug that the condition the drug was designed to correct may become more intense or severe.
- ◆ The person may become so unbalanced from the effects of a drug that another condition arises. This appears to create a need for another drug, which in turn produces more symptoms (called “side” effects by the medical profession), for which the person may be prescribed yet a third drug. And so on.
- ◆ The bodily function that the drug is replacing may decline, or altogether fail, from lack of activity. This deficit would then require immediate intervention—in the form of another drug or surgical replacement.

The medical phrase “side effects”—which really means *toxic* effects or *drug poisoning*—is deliberately misleading. *All* results and influences of medicines are “effects.” The pharmaceutical industry has fabricated the phrase “side effects” to discourage us from focusing on negative reactions to a drug.

Some “side” effects that the drug industry calls “toxic reactions” are actually *life-threatening*. Toxic reactions are said to occur when too high a level of the drug is in the person’s blood. But “toxic” means *poisonous*. A toxin is a poison. If a drug is poisonous, isn’t *any* level of the substance in the blood “too high”? Chemist Udo Erasmus comments, “Side effects (which are toxic reactions by our body to toxic substances) are not only acceptable, but

are the rule in drug-oriented medical practice, because all drugs are foreign to the body and therefore all drugs are toxic.”⁷ Drugs are toxic partly because they are synthesized from more complex substances that ordinarily take more time to work—and which contain “inactive” ingredients that help buffer (or eliminate entirely) the negative effects. I will say more about this shortly.

The foreignness of drugs to the body is also due to their broad-spectrum approach—an approach that conflicts with how the body processes its own internally produced biochemicals. Cellular biologist Bruce Lipton, author of *The Biology of Belief*, explains:

One of the most ingenious characteristics of the body’s sophisticated signaling system is its specificity. If you have a poison ivy rash on your arm, the relentless itchiness results from the release of histamine, the signal molecule that activates an inflammatory response to the ivy’s allergen. Since there is no need to start itching all over your body, the histamine is *only* released at the site of the rash. Similarly, when a person is confronted with a stressful life experience, the release of histamine within the brain increases blood flow to the nervous tissues, enhancing the neurological processing required for survival. The release of histamine in the brain to deal with stress behaviors is restricted and does not lead to the initiation of inflammation responses in other parts of the body. . . . [It] is deployed only where it is needed and for as long as it is needed.

But most of the medical industry’s drugs have no such specificity. When you take an antihistamine to deal with the itchiness of an allergic rash, the ingested drug is distributed systemically. It affects histamine receptors wherever they are located throughout the entire body. Yes, the antihistamine will curb the blood vessels’ inflammatory response, dramatically reducing allergic symptoms. However, when the antihistamine enters the brain, it inadvertently alters neural circulation that then impacts nerve function. That’s why people who take over-the-counter antihistamines may experience allergy relief and also the side effect of feeling drowsy.⁸

Viewed from this perspective, the ingestion of drugs can be analogized to pouring one hundred gallons of paint over the side of a house to make sure that it covers the window ledge, which was the only part of the house you wanted to repaint. Drugs can never be specific the way the body is, so you have to throw all the paint you can at the house and hope that some of it sticks where you want it to

go. This is why there are so many “side” effects—in other words, toxic reactions—from allopathic drugs.

A blatantly titled article called “Death By Medicine,” published in December 2003, was written by several luminaries in the functional medicine field: health advocate Gary Null, who hosted his own show on Pacifica Radio for years and then earned his doctorate; Carolyn Dean, with degrees as both a medical and naturopathic doctor; highly respected neurologist Martin Feldman; Debora Rasio, a medical doctor affiliated with a hospital in Rome, Italy; and Dorothy Smith, PhD (whose name was omitted from some of the reprints). This paper was republished in numerous journals (including a 2005 edition of *The Journal of Orthomolecular Medicine*), and can be downloaded for free from many websites. For this groundbreaking report, the authors closely examined government statistics and articles in peer-reviewed medical journals that addressed the efficacy or harm of all facets of American medical care. This included surgical procedures, medical devices, hospital stays, drugs wrongly prescribed, drugs properly prescribed, and more. After compiling and analyzing the data, the team presented its findings on whether people improved from the care they received, or developed additional illnesses due to physician error or drugs. The team also discussed the number of deaths due to medical services, deaths that could have been prevented, and even the financial costs of the errors. When working with much earlier studies, the authors adjusted for increases in population, changes in patient demographics, and other variables, by applying mathematical calculations to already existing data. In some cases, where two sets of data existed, they used the more conservative (lower) figure, giving our medical system a more favorable judgment despite indications that they should not.

What Null et. al. uncovered, however, and were forced to conclude, was truly shocking. Modern medicine in the United States frequently harmed more than it helped. As a result of doctor errors, equipment malfunctions, improper diagnoses, infections acquired in hospitals—and, of course, adverse drug effects, whether they were the “correctly” prescribed drugs or not—people were sicker, and suffered from more severe symptoms, after their first or second doctor visit.

Readers who already don’t think much of the medical establishment might not be surprised by the team’s findings. But for much of the public (and perhaps some doctors as well), *Death By Medicine* legitimized the growing perception that modern medicine has largely failed to accomplish its stated goals. The statistics could not be refuted, because the authors used surveys and clinical records from the medical community’s own physicians, as well as databases from government agencies.

Effectiveness of Drugs

Are drugs effective in treating the condition for which they were prescribed? (Keep in mind that “treating” is a loaded term, because in the allopathic world “treatment” can mean eliminating or lessening symptoms without addressing the cause of the problem.) Annemarie Colbin, a natural foods chef and health writer, reports that in one study, “over 600 commonly prescribed drugs in use for more than 20 years have . . . never proven effective by properly controlled studies.”⁹ But perhaps the most revealing indictment about the success rate of drugs is a now-famous admission from Allen Roses, senior executive at Europe’s largest drug manufacturer, GlaxoSmithKline. On December 8, 2003, he announced, to a roomful of investors at a meeting in London, England: “The vast majority of drugs—more than 90%—only work in 30% or 50% of the people.”¹⁰ Apparently, not one of the investors in the room was surprised. The story first appeared in British newspapers and was rapidly picked up by the BBC, which sent it to the United States—much to the delight of holistically-minded folks who generally don’t have such information available to them in the mainstream press.

Allen Roses . . . has admitted that most prescription medicines do not work on most people. . . . [and that] fewer than half of the patients prescribed some of the most expensive drugs actually derived any benefit from them. . . . It is an open secret within the drugs industry that most of its products are ineffective in most patients but this is the first time that such a senior drugs boss has gone public.¹¹

Roses had an interesting agenda when citing the low success rates of drugs. As vice-president in genetics at Glaxo, he wanted to identify who would and would not respond to a given drug by administering a simple, inexpensive genetic test, thus eliminating the guesswork involved in prescribing pharmaceuticals. “His comments,” the reporter remarked, “can be seen as an attempt to make the industry realize that its future rests on being able to target drugs to a smaller number of patients with specific genes.”¹² Ironically, in his desire to promote yet one more medical procedure, Roses openly and publicly told the truth about drugs.

Damaging Effects of Drugs

Let’s look at the *Physician’s Desk Reference* (or *PDR*®, as it’s more popularly called). The *PDR*® is a massive volume of several thousand pages. Written for and sold to doctors, it’s supposed to list all effects of all drugs. But it doesn’t. A medical doctor remarks:

Because the *PDR*® is mainly a collection of drug-company written package inserts, it omits a great deal of important information. The *PDR*® omits or underreports many serious side effects. It frequently omits information about proven-effective medication dosages that are lower and safer than the doses recommended by drug companies or usually prescribed by doctors. . . .

Nor does the *PDR*® provide any guidance whatsoever in selecting between the many drugs many drugs that might be used for medical conditions. And, although a new *PDR*® is published each year, many drug descriptions are not updated. Some of these descriptions contain information that is decades old.¹³

Even with the significant omissions, a glimpse into some *PDR*® entries—from either the book, or, more recently, the *PDR*® online—is very revealing. The following are just a few examples.

- ◆ Tetracycline. This widely used antibiotic causes lightheadedness, dizziness, headache, blurry vision, nausea, vomiting, diarrhea, inflammation of the colon, inflammation of the pancreas, rashes and lesions of the skin, abnormal sensitivity to light, muscle and joint pain, water retention, asthma, fever, violent cough, chest constriction, variations in pulse, anemia, abnormal decrease in the number of blood platelets, inflammation of the membrane surrounding the heart, and serious shock. Tooth discoloration and abnormal development of tooth enamel occur in children. Some people also experience lesions and itching in the anal and genital regions. Antibiotics do not distinguish between the harmful bacteria we want to eliminate and the beneficial intestinal bacteria that help us digest our food. When the intestinal tract is healthy, flora are plentiful and keep in check the fungal forms that normally live in the body. However, after the antibiotics destroy the beneficial bacteria, there is nothing to prevent *Candida*, *Monilia*, and other fungi from proliferating and causing many unpleasant symptoms, for which doctors often prescribe more drugs. The *PDR*® warns about the “side” effect of inflammatory lesions due to *Monilial* overgrowth, but doesn’t say why this occurs. It’s no accident that the word *antibiotics* is from the Greek, meaning “against life.”
- ◆ Paclitaxel. This highly poisonous drug, marketed under the brand name Taxol®, is used for women with ovarian and breast cancer. Taxol® causes disorders of the nervous system, low blood pressure, high blood

pressure, hives, suppression of bone marrow, chest pain, rapid irregular heartbeat, *grand mal* seizures, skin rash, muscular pain, diarrhea, intestinal obstruction and perforation, and hair loss (the latter in 87% of the patients). In one study, nausea and vomiting occurred in over half of the test subjects; in another, 78% experienced anemia, 37% required red blood transfusions, and several required pacemaker surgery. The *PDR*[®] bluntly states: “There is no known antidote for Taxol[®] overdose.”¹⁴ Perhaps the manufacturer feels that the life-threatening nature of the drug is justifiable, as in allopathic circles cancer has such a low rate of cure. Ironically, drug-induced symptoms occur in those least able to deal with additional stress in their lives: the very ill.

- ◆ Eskalith[®], known generically as lithium carbonate or simply lithium, causes many effects: excessive thirst, weakness, tremors, digestive disorders (nausea, vomiting, loss of appetite and stomach pain), kidney

atrophy, fever, ringing in the ears, gastrointestinal disorders, drying and thinning of the hair, blackouts, seizures, hallucinations, heart palpitations or slowed heartbeat, sexual dysfunction, joint swelling, dental cavities, body pain, thyroid dysfunction, diabetes, blindness, mental confusion, restless muscle movements (eyes, tongue, jaw or neck), itchy skin, and coma. The *PDR*[®] warns that symptoms of lithium toxicity “can occur at doses close to therapeutic levels” *as well as* “levels *within* the therapeutic range.” [emphasis added]¹⁵ But how “therapeutic” is it when the dose can poison someone? (See Sidebar, “Mental Illness or Lithium Mineral Deficiency?”)

- ◆ Ambien[®]. Otherwise known as zolpidem, Ambien[®] is a sedative or hypnotic. The drug’s ability to affect neurotransmitters (brain chemicals) may induce sleeplessness, even though the drug is marketed to treat insomnia. Other “side” effects include loss of balance and motor control, confusion, depression,

Mental Illness or Lithium Mineral Deficiency?

The term “mental illness” is applied capriciously—and incorrectly—by mental health professionals who use an allopathic medical model to label people’s mental, emotional and spiritual distress. History shows that the definition of “mental illness” usually depends on the prejudices and cultural conditioning of the person making the diagnosis.

Labels aside, emotional distress is very real. However, some of the ways in which this distress is treated can have devastating consequences. Mental hospitals commonly prescribe the pharmaceutical lithium *carbonate* (or sometimes lithium *citrate*) to treat bipolar disorder and manic depression. A typical dose of lithium carbonate provides over 1,500 mg of elemental lithium, which accounts for its many serious “side” effects.

Lithium the natural mineral is quite different from lithium the drug. The mineral helps the body utilize nutrients. It raises low white blood cell counts and alleviates liver disorders. It enhances the ability of nerve cell DNA to replicate, while hindering the ability of some viruses (including adenovirus, cytomegalovirus, Epstein-Barr, *Herpes simplex*, and measles) to replicate. The mineral lithium binds to aluminum, allowing it to more easily be excreted. Lithium also benefits the brain in major ways. It mitigates discomfort from migraines and cluster headaches. It protects the brain from the effects of heavy metals, pharmaceuticals, and pathogens. And it helps restore the brain signaling pathways that have been damaged by chemicals. Because the aging brain shrinks, lithium’s ability to promote brain cell regeneration and increase brain cell mass suggests its usefulness not only as an anti-aging nutrient, but also as a treatment for people with Alzheimer’s, senile dementia, and Parkinson’s.

German medical doctor Hans Nieper found that the mineral lithium, when bound to the salt *orotic acid*, becomes lithium *orotate*. Lithium orotate easily crosses the blood-brain barrier because the salt releases the lithium directly into the brain. Hence, much lower amounts of the mineral can be used with optimal effectiveness and no “side” effects. Lithium orotate, when taken in the amounts recommended by some holistic practitioners—140 mg three times a day—provides a total of only 15 mg of elemental lithium. Medical doctor Jonathan V. Wright advocates taking between 10 and 20 milligrams daily of lithium orotate or aspartate to help protect the brain from shrinkage, chemical damage, and cell death due to loss of blood flow (which can be caused by a stroke). Based on research from the Mayo Clinic and other institutions, Wright also suggests natural lithium (along with other nutrients) for treating alcoholism, fibromyalgia, gout, and hyperthyroidism. Some practitioners even prescribe homeopathic lithium.

Overwhelming the body is an invasive practice taught by allopaths. Giving the body what it needs is the standard of care for holistically-oriented professionals. Research shows that a major contributor to mental and emotional imbalances is a deficiency of the essential trace mineral lithium. Healthy water contains between 3 ppb (parts per billion) and 5 ppb of lithium, and unprocessed sea salt crystals contain minute amounts.

Eighty-five percent of people suffering from stress, emotional problems or physical illness are helped by lithium the mineral, not lithium the drug.

Medical error has been defined as an unintended act (either of omission or commission) or one that does not achieve its intended outcome, the failure of a planned action to be completed as intended (an error of execution), the use of a wrong plan to achieve an aim (an error of planning), or a deviation from the process of care that may or may not cause harm to the patient. . . . While many errors are non-consequential, an error can end the life of someone with a long life expectancy or accelerate an imminent death. . . . *If medical error was a disease, it would rank as the third leading cause of death in the US.* [emphasis added]

rapid heartbeat, and hallucinations. Some people who take this drug engage in activities that they don’t remember afterward. There have been reports of people walking, making phone calls, eating, having sex, and even driving while under the influence of this drug—activities of which they have no memory later.

Warnings about drugs are not confined to the *PDR*®. Medications come equipped with labels and lengthy inserts. The label for Azidothymidine—otherwise known as AZT and popularly prescribed to people infected with the HIV virus—reads in part: “Toxic by inhalation, in contact with skin and if swallowed. Target organ(s): blood bone marrow. If you feel unwell, seek medical advice. Wear suitable protective clothing.” Elsewhere the label reads: “For laboratory use only. Not for drug, household or other uses.”¹⁶ A skull-and-crossbones, the legal symbol indicating that this substance is a poison, also appears on the label. Unfortunately, many people never see these warnings because the medications are removed from their original boxes and repackaged by the pharmacist before reaching the consumer. If people did see the warnings for AZT, I wonder how many would take it.

Now let’s look at a popular medical textbook, *Harrison’s Principles of Internal Medicine*, for explicit warnings about the effects of drugs. Gastrointestinal distress, particularly vomiting and diarrhea, accounts for about one-third of the “side” effects of drugs. Another analysis reveals adverse drug reactions in a full 20% of ambulatory patients.¹⁷ However, these statistics were not only released over two decades ago, but they were obtained from *reported* cases only. The medical community acknowledges that the rate of reporting adverse drug reactions is much, much lower than the figures reflect.

Colbin reported that according to figures from as far back as 1986, “over 1 million people a year (3% to 5% of admissions) land in hospitals as a result of negative reactions to drugs.”¹⁸ And according to “Incidence of adverse drug reactions in hospitalized patients,” which appeared in the 1998 issue of *The Journal of the American Medical Association*, from 1966 to 1996, 2.2 million people had serious or fatal in-hospital, adverse drug reactions to prescribed medications.¹⁹ These statistics are significant because they were drawn from a stationary, captive group—people in hospitals—where, we have to assume, at least somewhat accurate records were kept. The 2.2 million does not reflect adverse reactions from unhospitalized people, or any reactions that weren’t reported.

Today there are even more noxious drugs and sicker people, due to environmental toxins and other factors. Levels and types of drug-related damage have accordingly increased. A more recent study from the *New England Journal of Medicine* shows that “an alarming one in four patients suffered observable side effects from the more than 3.34 billion prescription drugs filled in 2002.”²⁰ And the associate director at one of the FDA offices stated bluntly: “The 250,000 reports [of adverse drug reactions] received annually probably represent only 5% of the actual reactions that occur.”²¹ This means that there are nearly *five million* negative reactions each year to medicines.

It’s time to reconsider if the “side” effects of drugs are worth the benefits we might derive from them. Many people don’t even think to ask this question.

Administration of the Wrong Drugs

Not only do most drugs not work, but the wrong drugs are often administered. (Admittedly, these are arbitrarily separate categories. If most drugs don’t work, aren’t they the “wrong” drugs?) For example, Null et. al. found that the number of antibiotics prescribed yearly for viral infections was 20 million.²² Even one antibiotic prescription is significant, because it’s basic medical knowledge that antibiotics affect only bacteria and not viruses. Why, then, were antibiotics prescribed for viral infections—by physicians who should have known better?

Preparation of Drugs

I believe that it’s important to treat animals well—especially if we are using them to benefit us, such as provide ingredients for food or medicines. Even though this discussion is about the effects of drugs and not about animal welfare per se, how the animal is treated reflects the intentions and ethics of the manufacturer.

Premarin® is a popular drug used to help alleviate hot flashes and other discomfort in women going through menopause. The major ingredient in Premarin® is estrogen, and the drug's name is derived from how the ingredients are harvested: from the urine of pregnant mares. The methods used to obtain the raw ingredient illustrate how the needs of animals are aggressively ignored during the creation of a drug. *Townsend Letter* reports:

To produce Premarin®, pregnant mares are hooked up to rubber urine-collection bags and tethered in stalls so small they cannot turn around or lay down comfortably. They are forced to stay in this position for six months, while their bodies are producing the most estrogen. They are also deprived of sufficient water, in order to maintain the concentrated estrogen in the urine. Within days of giving birth in the spring, the mares are re-impregnated. Fertile mares may go through this process many times, over years in their lifetime. . . . The mares . . . are slaughtered once they can no longer become pregnant, or if they become too lame to stand in the small stalls.²³

I would think hard about the ethics of taking drugs obtained in such a manner, or prepared by a company that doesn't care about the comfort and well-being of animals. If a company disregards the welfare of animals, why should we believe that it cares about the welfare of its human customers? (Animal cruelty is also intricately connected to how vaccines are made. This is discussed later in the chapter in the section, **The Vaccine Controversy**.)

If You Must Take Drugs

Not all medicines are useless or dangerous. In an emergency, an appropriately prescribed medication can halt severe symptoms and even save someone's life—until, of course, suitable measures can be taken to help the body heal more gently on its own, over a longer time period. But medicines must be used with discernment. Freely administering a drug that has toxic effects, without understanding how the body came to malfunction in the first place, is irresponsible and reckless. Yet this is the standard approach of most Western-trained physicians.

Because of the toxic effects of drugs, it's no accident that suddenly and completely withdrawing a drug—or even simply lowering the dosage—can likewise negatively impact health in serious ways, and even cause death. If you're taking pharmaceuticals and want to reduce your dosage or eliminate a drug entirely, please seek supervision from an experienced health professional.

HOSPITAL PROCEDURES / TESTS AND THEIR EFFECTS

"Hospital procedures" includes all diagnostic tests and surgeries. Many procedures are not tested at all because it's simply *assumed* that they will work. (This is why medicine is sometimes analogized to a religion—because we are expected to accept many of its precepts on faith.)

The prevalence of surgery, especially in the US, may suggest that it's less dangerous than it actually is. Authors of *Our Bodies, Ourselves* suggest exercising "great caution" when deciding whether or not to have an operation.

Many public health researchers are convinced that excess surgery results from excess surgeons, since the US has both the most surgeons and the highest rates of surgery in the world. . . . Because virtually all surgical procedures are reimbursed by insurance and graded according to their complexity, surgeons have strong financial incentives to perform a lot of surgery, especially . . . difficult operations. Hospitals similarly benefit from concentrations of elective (non-emergency) complex surgeries. And, precisely because surgery has become so common, many people have internalized the surgical mentality ("When in doubt, cut it out") and are easily convinced that an operation is necessary.²⁴

Women not only take more medicines than men, they also undergo more surgeries. An astonishing one-third of US women have a hysterectomy (the removal of the uterus) before menopause! The routine removal of the uterus began with 19th century French doctor, Martin Charcot, who claimed that ten women per day suffer from hysteria. His solution was to remove the offending organ that he believed was the cause. He never considered that the source of their depression was cultural—the myth that women were inferior, and the resulting practice of keeping them confined to the house all day! The word "hysteria" is derived from the Latin word *hystera*, which means "uterus." Disrespect of women (sexism) still dominates the medical field in the 21st century.

Nonessential surgical procedures are called "elective surgery," or sometimes "controversial surgery." They are considered medically unwarranted because their perceived benefits are generally outweighed by the risks. Risks include anesthesia, stress from the body's being cut, infection, and the body's reduced ability to function once organs or other parts are removed. "Death By Medicine" reported that 30% of these elective surgeries are very likely unnecessary.²⁵ The figures today are higher.

Let's take a look at cesareans (C-sections). They're performed if it's merely *assumed* that the woman will have a hard time giving birth. But cutting open the abdominal cavity to extract a baby is major surgery. It's extremely painful, leaves massive scarring, and cuts through meridians—important energy channels in the body. Often, a skilled midwife or nurse can bring the baby into the correct position by administering a massage, either externally or through the vaginal canal itself.

A tonsillectomy—the removal of the tonsils (pockets of lymph tissue on either side of the throat)—is common in many countries, although US figures are the highest, at 530,000 people a year (mostly children). The nearby related adenoids may be removed as well. This surgery is so routine that most people don't question it. Tonsils are excised after they become swollen “too many” times, with an accompanying sore throat. But tonsils (and adenoids) are *designed* to get swollen! As part of the lymphatic network, during an infection these organs fill with immune cells to perform an important function: scavenge pathogens. New studies show that people who have had their tonsils removed are at risk later for significantly more infections, autoimmune conditions, and other chronic medical issues than people who keep their tonsils. Problems later in life include respiratory infections (asthma, bronchitis, chronic obstructive pulmonary disease and pneumonia) and even apparently unrelated conditions such as skin and eye infections and parasites. As it turns out, vital immune cells develop in the tonsils and adenoids. Removing these needed organs robs the body of a critical defense against all kinds of diseases.

Consider silicon breast implant surgery, classified as elective because it's not medically necessary. Foreign objects that don't belong in the body are inserted. If the implants leak, the silicon can cause almost any symptom from extreme joint pain to chronic fatigue.

Many diagnostic routines are also highly invasive and painful. Moreover, they can have long-term health consequences—a high price to pay, considering their limited value. Their innocuous-sounding label of “tests” diverts us from their danger. Consider a biopsy, during which living tissue is extracted from the human host (usually to detect cancer). This can create more problems than if the tumor had been left alone. Normally, the body encases cancerous cells with material that we call a “tumor,” to prevent the cancer from spreading. If the tumor is pricked or removed by surgery, cancerous cells can leak into the bloodstream, migrate, and proliferate elsewhere. If the immune cells aren't strong enough to

neutralize these stray cells, *metastasis* occurs. Biochemist Vincent Gammill, research director of the nonprofit Center for the Study of Natural Oncology in California and the inventor of many cancer vaccines and nutraceuticals, once remarked: “I rarely see distant metastasis until after a biopsy—and then it rapidly goes everywhere, including the bones.”²⁶ It's illegal for doctors to advise against a biopsy. If they do, they can lose their license.

One very common test, the Pap smear, consists of scraping cells from a woman's cervix (the lower end of the uterus) and checking those cells for abnormalities. Irregular cells are supposed to indicate cancer. Although the procedure isn't dangerous and doesn't hurt too much, it can often lead to false negatives or false positives. Incredibly, one study showed that up to “10 million women who have had hysterectomies and who no longer have a cervix are still getting Pap tests. . . . When a woman does not have a cervix, a doctor scrapes cells from her vagina instead, sending them off to be examined.” One doctor admitted, “It's a relatively cheap and easy procedure. It's sort of become a habit.” A more ethical doctor said she was “quite surprised [to hear about this]. . . . These women are being screened for cancer in an organ they don't have.”²⁷

Another test, the euphemistically-termed spinal “tap,” is called “lumbar puncture” by physicians. The colloquial name doesn't convey how risky and painful the procedure is, but the medical term does. During the puncture, cerebrospinal

fluid is extracted from the spine with a long needle. Examination of the fluid is then supposed to confirm (or deny) the existence of infections such as meningitis, brain bleeding or hemorrhage (blood would be present in the fluid), and neurological disorders such as seizures. People whose spines are “tapped” develop headaches, and pain, bleeding or infection at the injection site.

High on the list of dangerous “tests” are X-rays, which are so common in developed countries that most people aren't cautious. However, as analyzed by Null et al.:

When X-rays were discovered, no one knew the long-term effects. . . . It was common practice to use X-rays in pregnant women to measure the size of the pelvis, and make a diagnosis of twins. Finally, a study of 700,000 children born between 1947 and 1964 was conducted in 37 major hospitals. The children of mothers who had received pelvic X-rays during pregnancy were compared with the children of mothers who had not been X-rayed. Cancer mortality was 40% higher among the children with X-rayed mothers.²⁸

Removal of Healthy Breasts Is Found to Cut Cancer Risk

X-rays are dangerous because they consist of *ionizing radiation*—very short, high-frequency electromagnetic wavelengths that are so powerful, they knock electrons in atoms off their orbits. This causes permanent damage on the cellular level, leading to genetic mutations and cancer. “Even though by now it is popular knowledge that X-rays may cause cancer,” Colbin wrote, “over 300 million of them are ordered yearly *without medical need*. Radiation from diagnostic X-rays is implicated in cancer, blood disorders, tumors of the central nervous system, diabetes, stroke, and cataracts.”²⁹ X-rays, along with other tests such as CT scans, mammography and fluoroscopy, are cited by Null et. al. as “a contributing factor to 75% of new cancers.”³⁰

The mammogram—heavily marketed to women as essential to detect breast cancer early—is an X-ray. Mammograms are supposed to detect “spots” on the breast that don’t belong and are thus assumed to be cancerous. Mammograms are routinely promoted so that treatment for cancer can begin immediately. Not receiving a mammogram during a routine medical exam is regarded as abnormal, foolish, and dangerous. In fact, the American Cancer Society recommends that women over 40 years old get “screened” (another euphemistic word) annually. But in November 2009, the US Preventive Services Task Force (a federal advisory board) stated that annual mammograms for women under 50 years old weren’t necessary, and were needed only every two years after that.

Mammograms are unnecessary, dangerous, inaccurate, and costly. Note the title of a 2015 study, “National expenditure for false-positive mammograms and breast cancer overdiagnoses estimated at \$4 billion a year.”³¹ A mammogram cannot detect cancer in almost 73% of women whose breast tissue is exceptionally dense. Most women under 40 have dense breast tissue. A 2011 edition of *The Lancet Oncology* showed that women who received the most number of mammograms had a higher incidence of invasive breast cancer during the next six years than a control group who received fewer mammograms.³² A thermogram, which is a far infrared test that uses the body’s own heat to create images, is a safe, effective way to detect breast cancer; but it’s not publicized by doctors.

The statistics compiled by Null and colleagues have been confirmed by newer findings. In August 2013, the *Mayo Clinic Proceedings* described medical testing, procedures and treatments that didn’t produce the expected results. More than half were found to have no benefit, and many caused harm. “In a prior investigation of one year of publications in a high-impact [medical] journal, we found that . . . 46% constituted medical reversals [setbacks].”³³

Dangerous tests will continue as long as people consent to receiving them and are willing to pay for them.

IATROGENIC (DOCTOR-CAUSED) DISEASE AND PREVENTABLE DEATHS

Deaths resulting from overmedication, prescription errors, invasive testing, surgeries, and hospitalizations (someone catches an infection while being hospitalized, and dies), are so commonplace that there is a name for these occurrences: *iatrogenic illness* or *iatrogenic disease*. These deaths are even more tragic considering that 8.9 million people were hospitalized unnecessarily in the year 2001 alone.³⁴

Drug Iatrogenesis

Harrison’s Principles of Internal Medicine states that a “side” effect from drug-induced diseases—death—in hospitalized patients varies from 2% to 12%.³⁵ Each hospitalized person is given about 10 different drugs.

A 1998 study indicates that over 100,000 Americans a year die from harmful reactions to medications. The deaths “are not due to mistakes by doctors in prescribing drugs or by patients in using them. Rather, drug reactions occur because virtually all medications can have bad side effects in some people, *even when taken in proper doses*. [emphasis added] ‘We want to increase awareness that drugs have a toxic component,’ said Dr. Bruce Pomeranz, an author of the study and a professor of neuroscience at the University of Toronto. ‘It’s not rare.’”³⁶ There are other mistakes too. Null et al. cite a 2002 study showing that “20% of hospital medications for patients had dosage mistakes. Nearly 40% of these errors were considered potentially harmful to the patient. In a typical 300-patient hospital the number of errors per day were 40.”³⁷

Simply put, the fourth leading cause of death in America, after cancer, heart disease and stroke, is reactions to “safe” over-the-counter drugs and “properly” prescribed prescription medicine. Is the prescribing of most medicine, then, truly proper?

Will Doctors Take Their Own Medicine?

Professor John Saunders, who chairs the ethical issues committee of the Royal College of Physicians, certainly believes that there are circumstances in which doctors should be volunteers in their own trials. Having been a subject in his own research in the past, he says: “I think it is perfectly legitimate for people to say: ‘If you aren’t prepared to undergo this experiment on yourself, how dare you expect others to do so.’”

FDA Scientists Feel Pressured To Lie

The Union of Concerned Scientists (UCS) . . . released survey results that demonstrate pervasive and dangerous political influence of science at the Food and Drug Administration (FDA). Of the 997 FDA scientists who responded to the survey, nearly one-fifth (18.4%) said that they “have been asked, for non-scientific reasons, to inappropriately exclude or alter technical information or their conclusions in a FDA scientific document.” . . .

The UCS survey, which was co-sponsored by Public Employees for Environmental Responsibility, was sent to 5,918 FDA scientists. Forty percent of respondents fear retaliation for voicing safety concerns in public. This fear, scientists say, combines with other pressures to compromise the agency’s ability to protect public health and safety. More than a third of the respondents did not feel they could express safety concerns even inside the agency. . . . [Also:]

- ◆ 61% of the respondents knew of cases where “Department of Health and Human Services or FDA political appointees have inappropriately injected themselves into FDA determinations or actions.”
- ◆ Only 47% think the “FDA routinely provides complete and accurate information to the public.”
- ◆ 81% agreed that the “public would be better served if the independence and authority of FDA post-market safety systems were strengthened.”
- ◆ 70% disagree with the statement that FDA has sufficient resources to perform effectively its mission of “protecting public health . . . and helping to get accurate science-based information they need to use medicines and foods to improve their health.”

To address the concerns raised by FDA scientists, UCS recommends:

- ◆ **Accountability.** FDA leadership must face consequences if they side with commercial or political interests and not with the American people.
- ◆ **Transparency.** Scientific research and reviews should be open so any undue manipulation is immediately apparent.
- ◆ **Protection.** Safeguards must be put in place for all government scientists who speak out.

Hospital Infections

Back in 1986, Colbin reported “the most rapidly spreading epidemic of the 20th century,” citing “over 2 million infections a year” in American hospitals, that resulted in “60 to 80 thousand deaths.”³⁸ Data analyzed in 2002 by *The Chicago Tribune* from patient databases, court cases, 5810 hospitals, and 75 federal and state agencies, found “103,000 cases of death due to hospital infections, 75% of which were preventable.” [original emphasis]³⁹ By 2011, according to the Centers for Disease Control, the number of hospital-acquired infections (in hospitals solely devoted to acute care) had escalated to 722,000. Almost ten percent of those infected, died.⁴⁰

Deaths from Surgeries and Tests

Colbin wrote that an “estimated 2.5 million operations a year are performed without real medical need, resulting in some 12 thousand needless deaths.”⁴¹ Statistics compiled by Null and colleagues two decades later gave comparative numbers for unnecessary surgeries. In 1974, 2.4 million unnecessary surgeries were performed annually, resulting in 11,900 deaths. In 2001, 7.5 million unnecessary surgical procedures were performed, resulting in 37,136 deaths.⁴²

Combined Statistics

In 2003, Null et al. wrote that the total number of iatrogenic deaths yearly, in hospitals, is 783,936. The deaths were surgery-related, and were due to adverse drug reactions, (unspecified) medical error, bedsores, infection, malnutrition, and useless procedures. “We could have an even higher death rate by using [another statistician’s differently calculated] . . . medical and drug error rate of 3 million. . . . *The American medical system is the leading cause of death and injury in the United States.*” [emphasis added]⁴³

Is “Death By Medicine” still relevant? Consider this: a 2010 *New England Journal of Medicine* article found that 18% of people admitted to hospitals were injured by medical care (some repeatedly); over 63% of the injuries could have been prevented; and in about 2.5% of the cases, the problems caused, or contributed to, death. “We found that harms remain common, with little evidence of widespread improvement.”⁴⁴ An article in the September 2013 issue of *Journal of Patient Safety* pointed to another grim statistic: each year, between 210,000 and 440,000 people who are admitted to the hospital suffer some type of preventable harm that contributes to their death.⁴⁵ An even more recent statistic is in the Sidebar on page 26.

Do you have confidence in a hospital stay if you get sick?

DEATHS AND INJURIES FROM MEDICAL DEVICES

Medical devices include items placed inside the body (such as breast implants, replacement limbs and pins, bone grafts, pacemakers, and mesh used for patching internal holes), and products used externally (such as medical scanners, ventilators, infant resuscitators, insulin pumps, and defibrillators). Ordinarily, we might not consider that medical devices belong in the same category as unsafe prescriptions. But medical devices can be as injurious as pharmaceuticals. In the last several years especially, a number of well-known manufacturers have been sued for issuing devices and implants that were either defective, or made with substandard parts—which resulted in serious injuries or death. Pathogens on improperly sterilized instruments, such as duodenoscopes (which allow viewing of the stomach), also contribute to deaths.

According to the FDA's own website, each year the agency receives "several hundred thousand medical device reports of suspected device-associated deaths, serious injuries and malfunctions."⁴⁶ "Several thousand" is a lot of reports. Typically the FDA recalls defective products, but hospitals and individual doctors are allowed to decide if they want to stop using the products. Sometimes they don't. Let's review just a few devices in the past few years that have malfunctioned:

- ◆ A 2007 NBC News report on heart stents (used to widen blood vessels ridden with scars or plaque) called these devices "time bombs,"⁴⁷ because they irritate the body, causing scar tissue—thus exacerbating the very problem for which they were installed. People ended up taking blood thinning medications anyway.
- ◆ In 2012, the death certificate of a Boston, Massachusetts man initially indicated that he died from throat cancer. But it was later determined that too much morphine had dripped into his system all at once, due to a breakable plastic clip in his medicine dispenser that was supposed to regulate the flow of medication. A manufacturer's representative assured the hospital that although a new clip was needed, it was still safe to use the device. The item had been assigned a "Class 1" recall by the FDA—a useless regulation, because even with this most strongly worded recall it's not necessary to discontinue using a product that has been proven to cause injury or death.
- ◆ In 2013, a company called GE Healthcare was forced to tell customers to stop using more than 20 models of its nuclear imaging devices after some bolts became dislodged from one of its machines and killed someone.

FACTS AND FALLACIES ABOUT CLINICAL TRIALS

Standard scientific protocol for the early stages of drug testing involves inducing illness in two matched groups of animals. The researchers deliberately don't intervene in the first group (*control* group) to make sure that the disease really would have disabled or killed them. However, the researchers administer the experimental drug or treatment to the second group (*test* group) to see how many of those animals will live.

The ways in which drugs are tested have so many flaws that test results are not only misleading, but often invalid. In the next several pages, I will discuss a few practices that can lead to some glaringly inaccurate conclusions about the effectiveness and safety of drugs.

A Human is Not a Lab Rat

In the United States, scientists heavily rely on animals to test a new drug. Mice are very popular because they reproduce and mature into adults quickly. This allows researchers to observe the responses of their offspring, and compare the health of subsequent generations, in a brief period of time. Rodents are utilized so much that the phrase *lab rat* was born. Other animals, such as dogs, cats, monkeys and other primates, and sometimes pigs (whose heart and circulatory system are remarkably similar to that of humans), are also used in experiments.

Once the animal's tolerance for a drug is reached and its responses recorded, the researchers believe that they have learned something about the alleged safe upper limit for human beings. Assuming that the drug is now considered safe enough to be used on human beings, the animals might be killed. Then researchers can legally experiment on humans. These experiments are called *clinical trials*.

Experimenting on animals for the benefit of peoples' health raises difficult ethical issues. Many discoveries have been made because of an animal's sacrifice. Yet at what point does the animal's suffering outweigh the dubious possibility of a beneficial discovery? I bring this up because the moral issue of causing pain to a sentient creature overlaps with whether or not it is scientifically sound to experiment on animals in the first place. How accurate is it to take information learned about animals and apply it to humans?

The organ structure, gland function, biochemistry, and even psychological responses in animals (and of course size) can be very different from those in humans. Therefore, as some researchers already know, the value of data gleaned from animals' responses to drugs is questionable.

When Clinical Trials Damage Even Healthy Volunteers

The trial of a new drug in a London hospital that nearly killed six men three months ago . . . left them in intensive care for weeks. . . . All six trial subjects were moaning or screaming and begging for pain pills. . . . All required weeks of intensive care, suffering failure of their kidneys, lungs and circulatory systems.

The six men, who were all young and healthy just months ago, now suffer from serious medical problems, . . . [including] severely damaged immune systems that will probably leave them vulnerable to disease for life. . . . They have been unable to get any of the drug companies involved in the trial to cover their medical expenses, or provide compensation—other than a one-time payment of under \$20,000 apiece.

The six research subjects were given infusions of the new and unknown drugs only 10 minutes apart. Virtually all reviews of the trial have concluded that such new drugs should be given to one patient at a time, with long intervals in between, so that monitors can screen for serious side effects. . . . TeGenero, the small German bio-technology firm that developed the drug . . . filed for bankruptcy-court protection on July 4.

"Inquiries in Britain Uncover Loopholes in Drug Trials"
The New York Times, August 3, 2006

A Human is Not a Test Tube

Sometimes the researchers report that a drug accomplishes the desired effects *in vitro*, which is in a test tube or Petri dish. They cultivate microbial colonies in a nutrient broth to feed them—much as soil nurtures a plant—and then let the microbes interact with the drug while they watch the activity under a microscope. The drug might perform very well to kill the pathogens being studied.

The problem is, *in vitro* is very different from *in vivo*, which is inside a living body (human or animal). The body of a complex and changeable human, or even an animal, provides vastly different nutrients for a dangerous microbe than does a carefully cultivated, selected nutrient medium inside of a container. Nevertheless, even if the two produce different results—that is, the drug in a Petri dish works well but it doesn't work as desired in a living body—the medication may still be allowed on the market.

How is the Drug Administered?

During clinical trials, a drug intended for oral consumption might be given orally. Similarly, a drug intended for injection might be given via a needle intravenously or intramuscularly. But sometimes during testing, an oral drug is administered by injection. This is often done when researchers experiment on animals. Injection always puts higher concentrations of a substance into the body than oral dosing. Perhaps, then, the intention is to pump as much of the drug as possible into the animal—far more than could be forcibly fed even in a lifetime—to test the subject's upper limits.

The problem is, a substance that bypasses the digestive process and goes directly into the bloodstream can have completely different effects. Nevertheless, some researchers believe that injecting a drug that's supposed to be taken orally provides useful and accurate data for a clinical trial.

How Much of the Drug is Administered?

During drug testing, the amounts typically administered are greater than the amounts intended to be prescribed in a real life situation. This is because researchers are trying to discover the subjects' highest tolerance of a drug before adverse effects occur.

To What is the Drug Compared?

During clinical trials, the drug being tested is often compared to something that the company knows is inferior or unsuitable. The medication might be compared to another drug that doesn't work well, or to a placebo (more on that shortly). This is done to amplify the illusion that the drug is effective.

How Many Subjects are Tested?

There are three, and sometimes four, phases of a clinical drug trial. In any of the phases the drug can be administered (in two different strengths) against another already accepted therapy or against a placebo. (A placebo is a supposedly inert substance assumed not to have an effect. This will be discussed in more detail shortly.) The FDA website summarizes these phases:

- ◆ *Phase I Trials.* Researchers test a new drug or treatment in a small group of people (20 to 80) for the first time to evaluate its safety, determine a safe dosage range, and identify side [toxic] effects.

- ◆ *Phase II Trials.* The study drug or treatment is given to a larger group of people (100 to 300) to see if it is effective and to further evaluate its safety.
- ◆ *Phase III Trials.* The study drug or treatment is given to large groups of people (1,000 to 3,000) to confirm its effectiveness, monitor side [toxic] effects, compare it to commonly used treatments, and collect information that will allow the drug or treatment to be used safely.
- ◆ *Phase IV Trials.* Post marketing studies gather additional information including the drug's risks, benefits, and optimal use.⁴⁸

For Phase I, 20 research subjects is ridiculously insignificant. And for Phase III, 3,000 subjects—the maximum number reported for any of the steps—is inadequate, considering the millions of people who might eventually take the drug.

Sometimes the number tested does not even reach three thousand. For instance, the *PDR*[®] reports that one of the tests for the drug Taxol[®] (used for women with ovarian and breast cancer) consisted of only 83 subjects. According to the National Cancer Institute, one in eight women will get breast cancer during her lifetime.⁴⁹ Let's say that 1 in 50 people will be taking Taxol[®]. You do the math. What percentage out of even 1 in 50 people in the entire US population is 83 subjects?

If excessive smoking actually plays a role in the production of lung cancer, it seems to be a minor one.

—Dr. W.C. Heuper, of the National Cancer Institute, quoted in *The New York Times* April 14, 1954

For How Long are Subjects Tested?

Generally, the study ends when results are promising. But the time allotted for clinical trials is nothing compared to the extended periods during which people will be using the drug. Null et. al. wrote, “Serious adverse drug reactions commonly emerge after Food and Drug Administration approval. The safety of new agents cannot be known with certainty until a drug has been on the market for many years.”⁵⁰

“Post-Approval” is a fifth step of drug testing, but it's not part of the actual approval process. Post-Approval is a little like closing the barn door after the horse has escaped. Null et al. reported that “The General Accounting Office (an agency of the US Government) found that of the 198 drugs approved by the FDA between 1976 and 1985, . . . 102 (or 51.5%) had serious post-approval risks.” These “risks” included “heart failure, myocardial infarction, anaphylaxis, respiratory depression and arrest, seizures, kidney and liver failure, severe blood disorders, birth defects and fetal toxicity, and blindness.”⁵¹

Do the Study Subjects Represent the General Population?

Common sense indicates that the people tested for a drug's effectiveness should have the illness that the drug is designed to treat. But often, clinical drug trials are conducted on healthy people. This skews the results. Healthy individuals tend to be more resistant to negative effects of drugs; whereas sick individuals—the ones who will actually be taking the medication—have lowered resistance due to their compromised immune response.

When sick people do participate in drug trials, they are carefully evaluated first. The ones who are selected to participate have been assessed by the researchers to be most likely to benefit from the drug. This is not a random acceptance of subjects, but a deliberate selection to give the drug trials the best possible outcome.

What If More Than One Drug Is in the Mix?

As already mentioned, drugs are often tested on healthy subjects. Such individuals will not be taking other medications. This is actually one of the requirements for a valid test, because researchers want to obtain a “pure” reading of effects without the interference of other drugs in the body.

The problem is, many people who are on medications either take more than one at the same time, or more than one within minutes or just a few hours of each other. There are no provisions during clinical trials to test the interaction of the officially tested drug with other drugs that are not being tested. Therefore, in real life, it may be difficult to know which chemical is producing the bulk of the undesirable symptoms.

Here is an illustration of the above problem. Take paclitaxel, a drug often used for cancer. Physicians are advised to treat patients with corticosteroids and other toxic chemicals before administering the paclitaxel itself, considered to be the “main” drug. (Note: Because the body has to be “prepped” in order to accept the medication, this indicates that the presence of the drug in the system is highly unnatural. Nonetheless, the *PDR*[®] states: “Paclitaxel is a natural product with antitumor activity.”⁵²) The negative reactions that the person experiences later could be exponentially increased by the interactions of the paclitaxel and the drugs that were used to “prep” him or her. It's impossible to know which reactions were caused by the paclitaxel and which were due to the “prepping” agent.

Is a Placebo Really Inert?

A clinical trial is usually conducted using two groups. One group is given the drug. The second group is given something else that appears to be a drug, but is supposedly inert and therefore doesn't have any "real" (recognizable) effect. This phony drug is the *placebo*. Researchers regard the placebo as a neutral control, against which they can compare the activity of the actual drug. To make the test objective, the participants don't know what they are receiving. Even the researchers who administer the substances don't know what they are giving, to prevent any preconceptions they might have from psychologically influencing the subjects, even on a subtle or unconscious level. It's well known that if placebo subjects believe that they are being given the actual (helpful) medicine, their belief will assist with healing. More on this in a moment.

The dictionary defines *placebo* as "a medicine given merely to humor the patient; especially, a preparation containing no medicine but given for its psychological effect."⁵³ *Placebo effect* is defined by the National Center for Complementary and Alternative Medicine at the National Institutes of Health (NIH) as "desirable physiological or psychological effects attributable to the use of inert medications."⁵⁴ A placebo is understood by both health professionals and the lay public to be totally inert, inactive, and thus harmless. But the so-called placebo method contains several serious flaws.

Placebos are often sugar pills. Sugar is hardly inert, especially not if the subject has diabetes, hypoglycemia, or weight or metabolic issues. Plus—and here's the astonishing disclosure—regardless of what the word means or what we think it means, *by law a placebo is not required to be inert*. Drug companies are permitted to design placebos with whatever ingredients they choose. And the drug companies are not required to disclose what those ingredients are. Sometimes, writes a reporter, the pharmaceutical companies put selected ingredients into

placebos that match those in the drug and will affect the outcome of the trial . . . [because they] are often fully aware of many of the side effects of the products they're testing. So, for instance, if a drug is known to cause dizziness and hypertension, the drug company running the test wants the placebo to have the same side effects. And they have an explanation for this. They say the placebo should mimic the drug being tested so that the control group of the experiment will have side effects similar to the placebo group. Without that, they claim, the results of a blind study would be compromised.⁵⁵

Manufacturing a so-called placebo so that it will induce "side" effects makes no sense from a scientific standpoint. But it makes a lot of sense if a company is trying to make a drug appear better than it actually is. The drug's harmful "side" effects can be masked if the control group is given something that induces similar harmful symptoms. This is why, when manufacturers of HPV vaccines were "testing" them, their control groups received placebos containing (hardly inert) aluminum.

Medical doctor and research professor Beatrice Golomb is a highly vocal proponent for changes in how drug companies conduct their tests. She wants them to disclose all placebo ingredients, as well as develop a standardized set of placebos whose ingredients and "side" effects are known. This is an excellent goal. However, trying to identify, and then rectify, all the problems intrinsic to drug testing involves a huge amount of effort and time. It might be more useful to devote energy to eliminating the need for drugs in the first place.

The Underestimated Effects of Water

One aspect of a clinical trial that influences any result is the simple ingestion of water. Even if a subject is swallowing a genuinely inert pill or tablet placebo, the water being drunk with the counterfeit medication is likely to have a beneficial effect on the subject's system. This is because so many people are chronically dehydrated. According to most sources, a deficit of even 2% of the water in the body severely impedes the ability to perform, both physically and mentally.⁵⁶ The late physician Fereydoon Batmanghelidj gave the figure as low as 1%. He observed that replenishing that missing 1% not only often mitigated disease, but even eliminated it entirely.⁵⁷ Similarly, the presumably neutral *saline solution* placebo sometimes injected into people could be just what they need. (See Chapter 3, **Water**, for more information.)

The Paradox of Double-Blind Studies

The relationship between belief and biological functioning is relevant to double-blind studies as well as placebos. One Chinese medicine researcher writes:

The Regeneration principle [of Chinese medicine] asserts that we must take an active role in our own healing; the double-blind principle asserts that we must *not*. . . . [It] keeps us blind precisely so we *can't* take a role. There's evidence that the double-blind design puts patients into a state of uncontrollability, or helplessness, which provokes

those high levels of corticoid hormones [that arise in response to stress]. . . . In that sense, the double-blind research design is unhealthful.⁵⁸

Put another way, double-blind studies actively suppress the immune function of the subjects. Thus, researchers who believe that they are gathering objective data are unknowingly contaminating the test results by preventing subjects from participating in their own healing. It should be obvious that actively interfering with someone's healing process is both unscientific and unethical.

We are commonly taught that the scientific method is linear: Cause 1 + Cause 2 = Effect. In reality, the scientific method is like a circle, where many elements interact with other elements. You can pick one point on the circle, and as you travel around the circumference you are led to every other point. Whole, living systems, such as human beings, are not linear. Very rarely, if ever, does a clear-cut case of "cause and effect" occur, because each body part and system is related to other body parts and systems. This interdependence of all parts in a living system is not linear.

Unfortunately, this truth does not dissuade many researchers from engaging in linear thinking to the exclusion of all else. Ironically, they do not realize that linear thinking prevents them from being scientific!

Clinical Drug Trials Are Not Registered with the Government

After the year 2000, a US federal law was enacted that required drug companies to post all research pertaining to the safety and efficacy of drugs on a government database. However, compliance has been only partial. For example, in July 2004, ABC News reported the FDA's discovery that "less than half of the total number of cancer drug therapy studies in 2002 were listed." The percentage of disclosure for *all* clinical trials was even lower. "Of more than 5,500 currently ongoing drug studies, only 13% were listed on the governmental database. The database wasn't intended to be comprehensive." Why not? What about the law? The report's conclusion: "It's unclear how to make firms comply because federal law prescribes no penalties for a company's failure to post results."⁵⁹

No Clinical Trials, but a Drug is Marketed Anyway

The FDA is known for approving drugs that haven't been properly tested over a long enough period, or with enough test subjects. An illuminating article, "New Drugs Hit the Market, but Promised Trials Go Undone," appeared in the March 4, 2006 edition of *The New York Times*.

When it approves new drugs for sale, the Food and Drug Administration often requires their manufacturers to study whether they are working as intended and whether they have unwanted side effects. But the agency reported . . . that two-thirds of the studies had not even been started.

. . . [The] director of the Office of New Drugs at the agency . . . emphasized that only 5% of the promised drug trials were officially considered "delayed." In many cases, trials have been pending for more than a decade but are not considered delayed because the agency never insisted on a specific timeline for the tests. . . . The agency often compromises by approving a drug quickly and then insisting that its maker prove after approval that the drug actually works. This strategy . . . has been only marginally successful.

As of September 30, of the 1,231 promised drug trials, 797, or 65%, had not begun or were "pending," according to the FDA. Another 231 were considered "ongoing" and 28 were "delayed." In the 2005 fiscal year, drug makers completed and submitted the results of 172 trials, the agency reported.⁶⁰

Note that the FDA has clout if it chooses to use it. The author stated that if pharmaceutical companies tend to be a little "delayed" in submitting test results to the FDA after their products are already on the market, they do "complete trials rapidly when the FDA demands the results as a condition for approval."⁶¹

Even more problems exist with drug trials. Many people with cancer are afraid to receive a placebo they don't believe will be as effective as the actual drug, so not enough cancer subjects enroll in clinical trials. Due to this shortage of test subjects, few cancer drugs are even assessed. (Ironically, new cancer drugs that are thought to produce similar effects to already existing drugs still tend to be tested.) Also, drug trials are expensive. Pharmaceutical manufacturers may be reluctant to invest more money in

- ◆ More than 50% of Americans take two prescription drugs.
- ◆ A full 20% take five or more prescriptions.
- ◆ Antibiotics, antidepressants and painkilling opioids are the most commonly prescribed drugs.

a drug, and therefore do not finish the test—even though, presumably, we need the test to be completed in order to know if the drug did or did not work. Finally, even though common sense suggests that the FDA should withdraw a drug from the market because there’s little or no proof of effectiveness—not to mention the shortage of test subjects, which invalidates the entire trial—regulators allow this unproven drug to be sold and used anyway, because they don’t want to “hurt the patients”!

Off-Label Use of Drugs

Sometimes a doctor prescribes a drug for *off-label* use. This means that even though the medication was created and tested solely for a specific conditions (or a few conditions), the person is choosing to use it for an entirely different reason. Pharmaceutical companies routinely encourage off-label use. Doctors are legally permitted to prescribe any drug, so off-label uses happen more frequently than one might think. Critics of off-label use comment on the “frequently inappropriate and non-tested uses of these medications in spite of the fact that these drugs are only approved [and presumably tested] for specific conditions.”⁶² These objections are unfounded for several reasons. One, most clinical trials are deeply flawed anyway. Two, one can experience “side” effects regardless of the stated reasons for taking the drug. Three, sometimes a drug works better for an off-label use than for the condition for which it was created. Nevertheless, given the harm that so many drugs cause, there is a chance that an off-label use could be dangerous.

The Hard Truth: A Summary

Most drugs don’t work as advertised. The majority of drugs are harmful. Clinical trials, due to many flaws in their methodology, do not accurately depict the dangers or effectiveness of a drug. If studies are published, the manufacturer chooses which information is released. Some details, or even an entire study, may be deleted because the outcome contradicts the desired result. The manufacturer may even fabricate results to make the drug appear less dangerous and more effective than it actually is. Researchers may choose to analyze the same data differently until the desired outcome can be reported.

A US federal law requires drug companies to reveal the results of all tests. However, there is no way for the FDA to determine or enforce compliance. And there is no punishment if the manufacturer fails to comply. Generally, a drug requires ten years of use before its safety can be determined. But because drugs are released much sooner, enormous damage may have already been inflicted.

Finally, as the FDA itself states, it’s not the agency’s job to conduct independent tests that might challenge the manufacturer’s claims. Independent testing facilities don’t exist because no money is made from challenging drug manufacturers. (Also, as I’ll discuss shortly, many FDA heads used to be employed by the very pharmaceutical companies they currently monitor; so there’s no incentive to conduct such tests anyway.)

For all these reasons, and more, the authors of “Death by Medicine” wrote: “Unfortunately, partaking in allopathic medicine itself is one of the highest causes of death as well as the most expensive way to die.”⁶³

HOW DRUGS ARE APPROVED

Once clinical trials are conducted, how exactly does the approval process work? This is worth knowing because in the mind of the public, approval equals safety—even though this assumption is usually not supported by facts. (Although our discussion is about the approval process in the United States, most other countries imitate the US.) In *World Without Cancer*, G. Edward Griffin explained:

There is a great deal of evidence supporting the nutritional-deficiency concept of cancer—more than enough to convince most people that the thesis is proven. But the word *proven*, when used by the FDA, has an entirely different meaning. . . . When the FDA says a therapy is proven, it means only that its promoters have complied with the testing protocols set by the agency to demonstrate safety and effectiveness. . . . [However] the successful completion of those tests does not mean, as the terminology implies, that the therapy is safe and effective. It merely means that tests have been conducted, the results have been evaluated, and the FDA has given its approval for marketing, often *in spite of* the dismal results.⁶⁴

As we have seen, the FDA’s system of approval for pharmaceuticals is loaded with flaws and loopholes. One major loophole is that FDA approval of drugs (or additives, or any substance under its jurisdiction) is based on reports—which may or may not be legitimate, unbiased research—that are *submitted by the manufacturer*. Many people believe that these clinical trials are serious scientific research, even though the studies selectively emphasize information or omit it altogether, making them misleading at best and outright false at worst. Thus, contrary to popular belief, FDA approval seldom guarantees safety.

THE PHARMACEUTICAL INDUSTRY'S ALLIANCE WITH THE FDA

Since the first edition of this book was published, the amount of reported corruption in the drug industry has skyrocketed. Across the nation and around the world, newspapers, magazines, television and the Internet have regularly carried exposés on doctors who have accepted bribes and gifts, drug companies plagued with lawsuits, pharmaceuticals that have failed to work and instead have caused serious harm, and the drug industry's influence in government. The following report, "FDA Advisers Tied To Industry," provides a good summary:

More than half of the experts hired to advise the government on the safety and effectiveness of medicine have financial relationships with the pharmaceutical companies that will be helped or hurt by their decisions, a *USA Today* study found. These experts are hired to advise the Food and Drug Administration on which medicines should be approved for sale, what the warning labels should say and how studies of drugs should be designed.

The experts are supposed to be independent, but . . . 54% of the time, they have a direct financial interest in the drug or topic they are asked to evaluate. These conflicts include helping a pharmaceutical company develop a medicine, . . . serving on an FDA advisory committee that judges the drug, . . . stock ownership, consulting fees or research grants.⁶⁵

It's against the law for the FDA to use experts with financial conflicts of interest, but the agency waived this restriction more than 800 times from January 1, 1998 through June 30, 2000. "At 92% of the meetings, at least one member had a financial conflict of interest. At 55% of meetings, half or more of the FDA advisers had conflicts of interest." "With few exceptions," the FDA followed the advice of the approximately 300 pharmaceutical "experts" on the eighteen advisory committees.⁶⁶ It's staggering to think that the (then) FDA senior associate commissioner Linda Suydam repeatedly waived the conflict-of-interest restrictions because, she claimed, no better experts could be found than the ones who were also hired by industry!

"New Drugs Hit the Market, but
Promised Trials Go Undone"
The New York Times, March 4, 2006

High-ranking FDA personnel have always been in the news. Daniel Troy had been associated with a Washington, DC law firm, helping drug and tobacco companies circumvent FDA regulations. After becoming chief counsel to the FDA in 2001, Troy invited drug companies to inform him of lawsuits against them—so the FDA could help defend them. Troy also filed briefs defending four drug companies (including Pfizer, SmithKline Beecham Consumer Products, and GlaxoSmithKline) that were being sued for damages by people who had used their products. Troy did his best to hide his ties to Pfizer: he did not tell Congress that Pfizer had paid him \$358,000 in 2001, the same year he'd been appointed to the FDA. After his infractions were revealed in 2004, he resigned.

Lester M. Crawford, MD, another FDA executive, made the news in 2006. He and his wife owned stock in pharmaceutical companies—despite the fact that, *The New York Times* reported, "Senior employees of the [FDA] are prohibited from owning shares in companies the agency regulates."⁶⁷ The Crawfords owned shares in Johnson & Johnson, Merck, Pfizer, Medtronic, and Boston Scientific, as well as shares in more diversified companies that sell health care products: Kimberly-Clark, Pepsico, Wal-Mart, and Sysco. Crawford was charged with, and pleaded guilty to, breaking conflict-of-interest laws, failing to report his stock ownership, and lying to the Justice Department. The article further revealed, "During a period when the Crawfords held shares in Pepsico, a soft drink and snack food company, he was chairman of an FDA Obesity Working Group that among other tasks was reviewing calorie content labeling for soft drinks."⁶⁸ Crawford did not go to jail. He was simply ordered to pay a fine—which no doubt he could easily afford, considering how lucrative dividends from pharmaceutical stocks are. (See Sidebar, page 41, "The True Cost Of Your Prescription Drugs.")

Since the early 2000s, the corruption has not stopped or abated. If anything, it has gotten worse. In 2014, *The Milbank Quarterly* published "Revisiting Financial Conflicts of Interest in FDA Advisory Committees." The author reviewed the voting behavior and financial interests of almost 1,400 FDA advisory committee members who helped approve drugs from 1997 to 2011. "Committee members who serve on advisory boards for sponsoring firms show particularly strong pro-sponsor bias." The probability of approval skyrocketed up to 84%.⁶⁹

The Real FDA

Reading the FDA's inspection files . . . [is] a seemingly endless stream of lurid vignettes . . . Faked X-ray reports. Forged retinal scans. Phony lab tests. Secretly amputated limbs. All done in the name of science when researchers thought that nobody was watching. . . .

When the FDA finds scientific fraud or misconduct, the agency doesn't notify the public, the medical establishment, or even the scientific community that the results of a medical experiment are not to be trusted. . . . As a result, nobody ever finds out which data is bogus, which experiments are tainted, and which drugs might be on the market under false pretenses. The FDA has repeatedly hidden evidence of scientific fraud not just from the public, but also from its most trusted scientific advisers, even as they were deciding whether or not a new drug should be allowed on the market. Even a congressional panel investigating a case of fraud regarding a dangerous drug couldn't get forthright answers. For an agency devoted to protecting the public from bogus medical science, the FDA seems to be spending an awful lot of effort protecting the perpetrators of bogus science from the public. . . .

As part of my investigative reporting class at New York University, my students and I set out to find out just how bad the problem was . . . We didn't have to search very hard to find FDA burying evidence of research misconduct. Just look at any document related to an FDA inspection. . . If you manage to get your hands on these documents, you'll see that, most of the time, key portions are redacted: information that describes what drug the researcher was studying, the name of the study, and precisely how the misconduct affected the quality of the data are all blacked out. . . . My students and I looked at FDA documents relating to roughly 600 clinical trials in which one of the researchers running the trial failed an FDA inspection. In only roughly 100 cases were we able to figure out which study, which drug, and which pharmaceutical company were involved. (We cracked a bunch of the redactions by cross-referencing the documents with clinical trials data, checking various other databases, and using carefully crafted Google searches.) For the other 500, the FDA was successfully able to shield the drugmaker (and the study sponsor) from public exposure.

It's not just the public that's in the dark. It's researchers, too. And your doctor. As I describe in the current issue of *JAMA Internal Medicine*, my students and I were able to track down some 78 scientific publications resulting from a tainted study—a clinical trial in which FDA inspectors found significant problems with the conduct of the trial, up to and including fraud. In only three cases did we find any hint in the peer-reviewed literature of problems found by the FDA inspection. The other publications were not retracted, corrected, or highlighted in any way. In other words, the

FDA knows about dozens of scientific papers floating about whose data are questionable—and has said nothing, leaving physicians and medical researchers completely unaware. . . . It's not just one study, either. . . . The FDA is keeping mum, even as wrongful-death lawsuits begin to multiply.

The FDA's failure to notify the public is not merely a sin of omission. . . . The agency regularly calls in advisers to get advice, or, more cynically, to get cover, about a decision the agency has to make. . . .

The FDA has a history of not notifying the public about the misconduct it finds. About a decade ago, the agency got into trouble over a newly approved antibiotic, Ketek. Inspectors had found extensive problems (including fraud) affecting key clinical trials of the drug. Yet the agency did its best to hide the problems from even its most trusted advisers. As David Ross, the FDA official in charge of reviewing Ketek's safety, put it, "In January 2003, over reviewers' protests, FDA managers hid the evidence of fraud and misconduct from the advisory committee, which was fooled into voting for approval." However, when the reports of misconduct at one clinical site began appearing in the press—along with stories of liver damage and blurred vision associated with the new drug—Congress stepped in, demanding information from the agency about the fraud. But even the Senate couldn't wring key information about the misconduct out of the FDA. "Every excuse under the sun has been used to create roadblocks," complained an indignant Senator Charles Grassley, "even in the face of congressional subpoenas requesting information and access to FDA employees." . . . In the decade since the Ketek affair, it's hard to see any change in behavior by the agency. . . .

[Another time] . . . a research firm named Cetero had been caught faking data from more than 1,400 drug trials. . . . But even after the agency exposed the problem, we found fraud-tainted data on FDA-approved drug labels. (The FDA still maintains its silence about the Cetero affair. . . . the agency refuses to release the names of the 100-odd drugs whose approval data were undermined by fraud.) . . .

Why does the FDA stay silent about fraud and misconduct in scientific studies of pharmaceuticals? Why would the agency allow claims that have been undermined by fraud to appear on drug labels? And why on earth would it throw up roadblocks to prevent the public, the medical community, its advisory panels, and even Congress from finding out about the extent of medical misconduct? . . .

The most common excuse the agency gives is that exposing the details about scientific wrongdoing—naming the trials that were undermined by research misconduct, or revealing which drugs' approvals relied upon tainted data—would compromise "confidential

commercial information” that would hurt drug companies if revealed. . . . Another excuse I’ve heard from the FDA is that it doesn’t want to confuse the public by telling us about problems, especially when, in the FDA’s judgment, the misconduct doesn’t pose an immediate risk to public health. . . . But even the most paternalistic philosophy of public health can’t explain why the FDA would allow drug companies to put data on its labels that the agency knows are worthless, or to fail to flag bioequivalence problems in a publication that is specifically designed for the purpose of flagging those very problems.

The sworn purpose of the FDA is to protect the public health, to assure us that all the drugs on the market are proven safe and effective by reputable scientific trials. Yet, over and over again, the agency has proven itself willing to keep scientists, doctors, and the public in the dark about incidents when those scientific trials turn out to be less than reputable. It does so not only by passive silence, but by active deception. And despite being called out numerous times over the years for its bad behavior, including from some very pissed-off members of Congress, the agency is stubbornly resistant to change. It’s a sign that the FDA is deeply captured, drawn firmly into the orbit of the pharmaceutical industry that it’s supposed to regulate. We can no longer hope that the situation will get better without firm action from the legislature.

Ronald Kavanagh, with a BS in Pharmacology, a PharmD, and a PhD, was hired to review the safety of new drugs submitted to the FDA’s Center for Drug Evaluation and Research (CDER). However, he left his ten-year post in 2008 after repeatedly encountering massive corruption.

Managers at CDER have placed the nation at risk by corrupting the evaluation of drugs and by interfering with our ability to ensure the safety and efficacy of drugs. While I was at FDA, drug reviewers were clearly told not to question drug companies and that our job was to approve drugs. We were prevented, except in rare instances, from presenting findings at advisory committees. In 2007, formal policies were instituted so that speaking in any way that could reflect poorly on the agency could result in termination. If we asked questions that could delay or prevent a drug’s approval—which of course was our job as drug reviewers—management would reprimand us, reassign us, hold secret meetings about us, and worse. . . .

I frequently found companies submitting certain data to one place and other data to another place and safety information elsewhere so it could not all be pulled together and then coming in for a meeting to obtain an agreement and proposing that the safety issue is negligible and does not need further evaluation. . . . Sometimes we were literally instructed to only read a 100–150 page summary and to accept drug company claims without examining the actual data, which on multiple occasions I found directly contradicted the summary document. Other times I was ordered not to review certain sections of the submission, but invariably that’s where the safety issues would be. This could only occur if FDA management was told about issues in the submission before it had even been reviewed. In addition, management would overload us with huge amounts of material that could not possibly be read by a given deadline and would withhold assistance. When you are able to dig in, if you found issues that would make you turn down a drug, you could be pressured to reverse your decision or the review would then be handed off to someone who would simply copy and paste whatever claims the company made in the summary document. . . . FDA’s response to most expected risks is to deny them and wait until there is irrefutable evidence postmarketing, and then simply add a watered down warning in the labeling. [One time] a company clearly stated in a meeting that they had “paid for an approval.” . . .

Obviously in such an environment, people will self-censor. . . . the honest employee fears the dishonest employee. . . . After FDA management learned I had gone to Congress about certain issues, I found my office had been entered and my computer physically tampered with. [The FDA secretly spied on *many* of its own scientists, capturing thousands of revealing emails that these employees privately sent to lawyers, journalists and Congressmembers.] . . . I was threatened with prison . . . One [FDA] manager threatened my children . . . I was afraid that I could be killed for talking to Congress and criminal investigators. . . . Congress did put me in contact with the Justice Department, however, I don’t believe my complaints were taken seriously by the FBI or investigated. . . . I found evidence of insider trading of drug company stocks reflecting knowledge that likely only FDA management would have known. . . . I believe I also have documentation of falsification of documents, fraud, perjury, and widespread racketeering, including witnesses tampering and witness retaliation. Scores of criminal prosecutions, convictions, and very long prison terms for current FDA employees . . . [are] necessary.

THE PHARMACEUTICAL INDUSTRY'S ALLIANCE WITH OTHER GOVERNMENT AGENCIES AND OFFICIALS

The Food and Drug Administration is not the only government agency with fingers in the pharmaceutical money pot. The drug industry has contributed astronomically high sums to political candidates and officials already in office. Twelve years ago, the Center for Public Integrity—a nonprofit organization focusing on politics, immigration, worker rights and “national security”—had a different focus. It was investigating drug companies so it could educate people “with tools and skills they need to hold governments and other institutions accountable.”⁷⁰ Even though the data below is over ten years old, it’s worth reviewing because the strategies of the drug industry have not changed. (One has to wonder why the medical data is no longer on the CPI website.)

In the area of lobbying alone, the CPI reported that the pharmaceutical industry:

- ◆ Employed [between October 1998 and April 2005] . . . almost 3,000 professional lobbyists, more than “any other organized interest,” including insurance companies.⁷¹
- ◆ Engaged 1,291 lobbyists in 2004, “some 52% [of whom] were former federal officials.”⁷² “This included more than 50 former members from the House [of Representatives] and a dozen from the Senate.”⁷³
- ◆ Lobbied “on more than 1,400 congressional bills since 1998 and spent a whopping \$612 million during that period.”⁷⁴
- ◆ Spent nearly \$116 million lobbying the government in 2003, and \$123 million in 2004.⁷⁵
- ◆ Utilized, since 1998, “four and a half pharmaceutical industry lobbyists . . . for every member of Congress in office.”⁷⁶

The slang phrase *Big Pharma* has captivated the attention of drug industry critics and even been used in the mainstream press. This phrase is probably derived from the name of the trade association Pharmaceutical Research and Manufacturers of America, whose acronym is PhRMA. PhRMA, the tenth largest lobbying organization in the US, represents more than forty of the world’s best-known drug companies. The CPI reported that “besides its 38 in-house lobbyists, PhRMA employed 160 lobbyists . . . [from] 2003 to 2004. Since 1998, the organization used 64 different firms to lobby 35 federal agencies on 38 issues.” In addition, PhRMA spent more

than \$65 million on lobbying from October 1998 through April 2005.⁷⁷

Gifts to politicians have played a huge role in the pharmaceutical industry’s romance with government. A study of more than 25,000 public documents, conducted by CPI, revealed that members of Congress, their staff, and aides received almost \$50 million worth of 23,000 privately funded trips, and “repeatedly ignored travel disclosure requirements and House and Senate rules.”⁷⁸

FDA personnel were also courted. Although policy forbids employees from taking trips paid for by health-related companies, significant amounts were spent on gifts to FDA employees. The FDA used an “apparent loophole” in the law, stated the CPI, to accept over “\$1.3 million in sponsored travel since 1999 from groups closely tied to pharmaceutical and medical device companies.” This money was used to “fly and host agency employees. Eleven drug safety board members were among the travelers sponsored. . . . Nonprofit groups and universities with . . . ties [to Big Pharma] paid for roughly a third of the more than 3,600 trips taken by [FDA] officials.”⁷⁹

It’s common knowledge that Big Pharma regularly contributes large sums to political groups and candidates sympathetic to its advancement. Data analyzed by CPI showed that executives, employees and political action committees of drug companies:

donated more than a combined \$18 million to state political groups and candidates from 2001 to 2004. . . . Pharmaceutical companies also spent significant amounts themselves on campaign donations to state candidates [with] favored positions on issues important to the industry. Pfizer contributed more than \$3 million to candidates for state office over the period; Eli Lilly and GlaxoSmithKline each gave more than \$2.2 million.⁸⁰

Not all of the money the drug industry spends is reported to the Internal Revenue Service (IRS). In 2002, PhRMA gave \$41 million in political contributions to pro-drug industry candidates. According to a report issued by another monitoring group, Public Citizen, PhRMA failed to mention most of these contributions to the IRS. These contributions were funneled through organizations claiming to be advocacy groups for senior citizens, which exempted PhRMA from having to disclose funding sources. Not surprisingly, instead of being used to make the lives of elders easier, the money paid for ads that supported political candidates who were friendly to the interests of Big Pharma/PhRMA.⁸¹

The True Cost of Your Prescription Drugs

Did you ever wonder how much it costs a drug company for the active ingredient in prescription medications? . . . We did a search of offshore chemical synthesizers that supply the active ingredients found in drugs approved by the FDA . . . A significant percentage of drugs sold in the United States contain active ingredients made in other countries [and which may be contaminated with heavy metals and other impurities]. In our independent investigation . . . we obtained the actual price of active ingredients used in some of the most popular drugs sold in America.

So often, we blame the drug companies for the high cost of drugs, and usually rightfully so. But in this case, the fault clearly lies with the pharmacies themselves. For example, if you . . . bought the name brand, you might pay \$100 for 100 pills. The pharmacist might tell you that if you get the generic equivalent, they would only cost \$80, making you think you are “saving” \$20. What the pharmacist is not telling you is that those 100 generic pills may have only cost him \$10! . . . This helps to solve the mystery as to why they can afford to put a Walgreen’s [a combination pharmacy and convenience store] on every corner. The chart below speaks for itself.

Drug and mg dose	Retail (100 tablets)	Cost, active ingredients	Markup (%)

The True Cost of Your Hospital Stay

In America today, hospitals and doctors are blatantly ripping us off and they aren’t making any apologies for it. . . . Some hospitals mark up treatments by *1,000 percent*. . . . Basic medical supplies are being billed out at hundreds of times what they cost providers. For example, it has been reported that some hospitals are charging up to 30 dollars for a single aspirin pill. . . . These medical predators get their hands on us when we are at our most vulnerable. . . . In our lowest moments we are willing to pay just about anything to get better or to make the pain go away. And so they very quietly have us sign a bunch of forms without ever telling us how much everything is going to cost. Eventually when the bills come in the mail, it is too late to do anything about it. . . . US hospital charges continue to soar . . . *charging more than ten times the total cost—or almost \$1,200 per \$100 of the cost of care*. Meanwhile, the hundred priciest hospitals in the nation were found to have this cost ratio begin at *765 percent*, which is more than twice the national average of *331 percent*.

The Politics of Price Gouging

- ◆ The claim that drugs are a \$200 billion industry is an understatement. According to government sources, that is roughly how much Americans spent on prescription drugs in 2002. . . . But it does not include the large amounts spent for drugs administered in hospitals, nursing homes, or doctors' offices (as is the case for many cancer drugs). In most analyses, they are allocated to costs for those facilities. . . . So the \$200 billion colossus is really a \$400 billion megacolossus.
- ◆ The people hurting most are senior citizens. . . . In 2002, the average price of the 50 drugs most used by senior citizens was nearly \$1,500 for a year's supply.
- ◆ More people . . . trade off drugs against home heating or food. Some people try to string out their drugs by taking them less often than prescribed, or sharing them with a spouse. Others, too embarrassed to admit that they can't afford to pay for drugs, leave their doctors' offices with prescriptions in hand but don't have them filled. Not only do these patients go without needed treatment but their doctors sometimes wrongly conclude that the drugs they prescribed haven't worked and prescribe yet others—thus compounding the problem. . . . In one of the more perverse of the pharmaceutical industry's practices, prices are much higher for precisely the people who most need the drugs and can least afford them.
- ◆ In 2001, the ten American drug companies in the Fortune 500 list (not quite the same as the top ten worldwide, but their profit margins are much the same) ranked far above all other American industries in average net return, whether as a percentage of sales (18.5%), of assets (16.3%), or of shareholders' equity (33.2%). These are astonishing margins. For comparison, the median net return for all other industries in the Fortune 500 was only 3.3% of sales. Commercial banking, itself no slouch as an aggressive industry with many friends in high places, was a distant second, at 13.5% of sales. . . . The most startling fact about 2002 is that the combined profits for the ten drug companies in the Fortune 500 (\$35.9 billion) were more than the profits for all the other 490 businesses put together (\$33.7 billion). . . . When I say this is a profitable industry, I mean really profitable. It is difficult to conceive of how awash in money Big Pharma is.
- ◆ Research & Development (R&D) is a relatively small part of the budgets of the big drug companies—dwarfed by their vast expenditures on marketing and administration, and smaller even than profits. . . . The prices [that] drug companies charge have little relationship to the costs of making the drugs and could be cut dramatically without coming anywhere close to threatening R&D. . . . The biggest single item in the budget is neither R&D nor even profits but something usually called "marketing and administration." . . . In 1990, a staggering 36% of sales revenues went into this category, and that proportion remained about the same for over a decade. Note that this is two and a half times the expenditures for R&D.
- ◆ One could hope drug companies would decide to make some changes—trim their prices, or at least make them more equitable, and put more of their money into trying to discover genuinely innovative drugs, instead of just talking about it. But that is not what is happening. Instead, drug companies are . . . marketing their me-too [copycat] drugs even more relentlessly [as well as] pouring more money into lobbying and political campaigns.

The Truth About the Drug Companies: How They Deceive Us and What to Do About It, 2004

Big Pharma, reported CPI, also funds pending legislation, having contributed \$83 million "to lobby on the California health care and drug discount referendum issue in 2005."⁸² The referendum would have given discounts for prescriptions to low and middle-income people. On the surface, this discount may seem innocuous or even helpful. However, this bill allocated the funds from taxes foisted on taxpayers, with Big Pharma as the primary beneficiary. Fortunately, Californians defeated the bill.

In 2010, Americans for Campaign Reform posted a fact sheet (acrrreform.org) on the politician-drug industry

collaboration. And "Who Owns Congress?," an article in the non-mainstream magazine *Mother Jones*, succinctly divided up members of the United States Congress and Senate based not on political party affiliation, but on the industries that had given them money.⁸³ There are many politicians with conflicts of interest—that is, financial ties to Big Pharma. They support bills favorable to the drug industry in exchange for having been given huge sums of money for their election campaigns. After serving their political term, they might go to work for the drug companies.

THE PHARMACEUTICAL INDUSTRY'S ALLIANCE WITH UNIVERSITIES AND OTHER RESEARCH INSTITUTIONS

Big Pharma's Free Handouts

Marcia Angell, a respected medical doctor, was Senior Lecturer in Social Medicine at Harvard Medical School and Editor-in-Chief of *The New England Journal of Medicine*. In her 2004 book, *The Truth About the Drug Companies*, Dr. Angell recounts the liaisons between drug manufacturers, universities, and presumably objective medical publications.

Only a handful of truly important drugs have been brought to market in recent years, and they were mostly based on *taxpayer-funded* research at academic institutions, small biotechnology companies, or the National Institutes of Health (NIH). . . . [The Senate-approved Bayh-Dole Act] enabled universities and small businesses to patent discoveries emanating from research sponsored by the National Institutes of Health, the major distributor of tax dollars for medical research, and then to grant exclusive licenses to drug companies. . . . Bayh-Dole also transformed the ethos of medical schools and teaching hospitals. These nonprofit institutions started to see themselves as “partners” of industry, and they became just as enthusiastic as any entrepreneur about the opportunities to parlay their discoveries into financial gain. Faculty researchers were encouraged to obtain patents on their work . . . (assigned to their universities), and they shared in the royalties. . . .

As the entrepreneurial spirit grew, . . . medical school faculty entered into other lucrative financial arrangements with drug companies, as did their parent institutions. . . . These laws mean that *drug companies no longer have to rely on their own research for new drugs*. . . . Increasingly, they rely on academia, small biotech startup companies, and the NIH. . . . One of the results has been *a growing pro-industry bias in medical research—exactly where such bias doesn't belong*. [emphasis added]⁸⁴

The FDA protects the big drug companies and are subsequently rewarded, and using the government's police powers they attack those who threaten the big drug companies. People think the FDA is protecting them. It isn't. What the FDA is doing and what the public thinks it is doing are as different as night and day.

Bribes and Gifts to Doctors

Doctors have been wined, dined and courted in myriad ways by pharmaceutical industry representatives. In 2000, *The Journal of the American Medical Association* published a study revealing that “interactions between physicians and the pharmaceutical industry are not as innocuous as they seem. Pharmaceutical companies spend more than \$11 billion each year to promote and market drugs, an estimated \$8,000 to \$13,000 per physician per year.”⁸⁵ In 2006, a reporter wrote that drug companies “spend more than \$20 billion annually in the United States on marketing activities directed at doctors and other health professionals, which is more than five times what they spend on television ads.”⁸⁶

These billions of dollars are spent on meals, entertainment (during which reps give sales presentations), books, medical supplies, “consultation fees,” awards of airline miles, gasoline, and even Christmas trees. Perhaps the most insidious gift, however, comes in the form of conferences that offer continuing medical education (CME) credits. Every year or two, medical professionals are required to attend health-related seminars to obtain the necessary credits toward license renewal. The goal,

which is laudable, is to teach medical professionals the most current information and techniques in their areas of expertise. But there's guaranteed to be a conflict of interest when pharmaceutical companies offer seminars authorized to confer CME credit. One can only imagine what “education” is being fed to attendees as innovations in their field.

In February 2006, the *Chicago Tribune* reported similar perks offered to British physicians by sales representatives for Abbott Laboratories. The sales reps offered not only “lap dances” at an adult sex club, but treated more than 60 health professionals to Centre Court Wimbledon seats and greyhound race track tickets. In response, Britain's leading drug industry trade group, the Association of the British Pharmaceutical Industry, suspended Abbott's membership for at least six months. Although this suspension did draw public attention to the ethics violations, and the presumably small number of employees involved were fired (or resigned), Abbott was still permitted to sell drugs without restriction in the United Kingdom. The *Chicago Tribune* article described the behavior of the

Abbott employees and the doctors involved as “troubling . . . because it occurred after the industry said it would begin policing itself.”⁸⁷ Despite the copious negative press, and doctors’ public statements that they would disengage from drug industry influence, the problem persists. A national survey in the April 2007 issue of the *New England Journal of Medicine* found that 94% of doctors reported having some relationship with drug companies. Seventy-eight percent accepted drug samples; 18% received payments for “consulting”; 16% received payments for speaking; 15% were reimbursed for travel, food and lodging (identified as “meeting expenses”); and 7% accepted tickets to sporting or cultural events. A whopping 83% were treated to food or drink.⁸⁸

The billions spent each year by drug companies create loyalty to specific brands. One researcher, who reviewed 29 studies of interactions between doctors and the drug industry, found that the doctors’ practices were affected in four major ways:

Physicians prescribed a drug manufactured by the sponsor of a medical education program more frequently, hospitals increased their prescribing of a conference travel sponsor’s drug, residents increased “nonrational” prescribing of a drug following a meeting with a company representative, and attitudes about drug company representatives became more positive. The researcher noted that interactions between MDs and pharmaceutical representatives begin in medical school and continue at a rate of about four meetings per month.⁸⁹

Busy doctors find it difficult to remain informed about the latest developments in drugs, so their interaction with drug company reps expedites their “education.” Perhaps most troubling about this lack of ethics is the very real risk to people’s health—not to mention lives. Gifts lead to higher health care costs through the prescribing of expensive brand name, rather than generic, drugs. Even more troubling, doctors tend to select whatever new product has just been peddled to them.

There’s another unethical practice resulting from the physician-drug company marriage. A surprisingly large number of doctors hired by Big Pharma to test drugs recruit their own patients into the studies for a per-patient fee. Even after the physicians have been disciplined by state medical boards, drug makers continue to hire them. In one such case, psychiatrist Faruk Abuzzahab had his license suspended for seven months, and restricted for another two years, by the Minnesota Board of Medical Practice. The Board accused him of a “reckless, if not willful, disregard” for the welfare of 46 people in his care, five of whom died. One of the five—a man whom Abuzzahab was pressuring to participate in a clinical trial—refused; so the physician immediately discharged him from the hospital, even though the man was deteriorating and in fact was suicidal. Two weeks later, the man killed himself. Despite Abuzzahab’s record and the public disciplinary action, he continued to be employed by drug makers to run so-called clinical trials. In fact, in Minnesota alone, from 1997 to 2005, over 100 doctors who had been disciplined by the state medical board accepted, collectively, \$1.7 million from pharmaceutical companies.⁹⁹

The American Medical Association climbed into bed with the Rockefeller and Carnegie interests in 1908 for the praiseworthy purpose of upgrading American medicine . . . [and] has been sharing the sheets ever since.

The impact of this organization on the average physician is probably greater than even he recognizes. First of all, the medical student cannot obtain an MD degree except at a school that has been accredited by the AMA. . . . If he decides to become a specialist, his residency must conform to AMA requirements. . . . To prove his standing as an ethical practitioner, he must apply to and be accepted by his county and state societies in conformity with AMA [allopathic] procedures. AMA publications provide him with continuing education in the form of scientific articles, research findings, reviews and abstracts from medical books, . . . evaluations of new drugs, foods, and appliances.

The AMA spends millions of dollars per year for television programs to affect public opinion, maintains one of the richest and most active lobbies in Washington, spends many millions in support of favored political candidates, and is instrumental in the selection of the Commissioner of the Food and Drug Administration.

Who controls the AMA? Most people would assume that the dues-paying members control their own association, but nothing could be further from the truth. . . . [The permanent] leadership maintains firm control over . . . [resolutions put forth by reference committees] appointed by the Speaker of the House, not by the delegates [doctor members]. The committees are stacked to carry out the will of the leadership.

Altogether the AMA now derives over \$10 million per year in advertising, which is almost half of the Association’s total income. Who advertises in the AMA Journal and related publications? The lion’s share is derived from the Pharmaceutical Manufacturer’s Association whose members make up 95% of the American drug industry.

SOME TALES OF APPROVAL

The FDA is responsible for approving thousands of drugs per year; but we will explore its approval process by reviewing just one drug and one food additive. These two examples work very well to show the revolving door policy between FDA officials and drug company personnel—and in many cases, their attorneys too. As you read, keep in mind that there are hundreds, if not thousands, of drugs and additives whose stories are similar. The names of the products and personnel change, but the basic scenario is the same.

rBGH (or rBST)

Often, drugs are hastily approved because high-ranking FDA personnel are comprised of former or future drug company employees. The story of rBGH (recombinant bovine growth hormone) is particularly insidious, because after the drug was approved, a major media network as well as the manufacturer and the FDA attempted to suppress the truth about its dangerous effects. rBGH is not a typical veterinary drug. Intended to induce cows to produce more milk, it must be injected into the animals daily. But rBGH ends up in the food supply, so the average consumer is drugged each time milk, butter, cheese, cream, ice cream or yogurt are ingested.

rBGH was developed by Dr. Margaret Miller, one-time researcher for the chemical corporation Monsanto, which is famous for its drugs and pesticides. Rose Marie Williams, columnist for the holistic journal *Townsend Letter*, describes how the drug was developed:

Bovine Growth Hormone (BGH) is naturally produced by the pituitary gland in cows and stimulates milk production. The recombinant form (rBGH) is a genetically engineered combination of the cow gene for BGH and DNA from *Escherichia coli* (*E. coli*) bacteria. Therefore, it cannot be identical to the natural hormone produced by the cow as is claimed by Monsanto.⁹¹

The recombinant form of Bovine Growth Hormone was easy to approve at the FDA. After she finished her work at Monsanto, Miller was hired as part of the FDA staff, where she was put in charge of evaluating her own research. “FDA’s standard cancer test for a new human drug requires two years testing on several hundred rats,” Williams writes, but the artificial hormone “was tested for only 90 days on 30 rats before being approved.”⁹²

As one might expect, with such shoddy testing there was bound to be trouble. Although some dairy farmers

reported positive experiences with the drug, more than half did not. Among at least 20 adverse effects were a 79% increase in mastitis (inflammation of the udder, which raises the amount of pus in the milk), increased digestive upset including diarrhea, higher incidence of lameness, more metabolic disorders, and increased multiple births. The damage was not borne solely by the cows, either: humans who consumed dairy products from these cows also developed health problems, including higher than usual incidences of colon, lung, prostate and breast cancers as well as a dramatic increase of multiple births.

Attempts to disclose this data on a mass scale were heavily resisted. In late 1996, Fox Television wife-and-husband journalist team Jane Akre and Steve Wilson were assigned to do a story reassuring consumers that rBGH was safe. Much to their surprise, after interviewing dairy farmers and reviewing studies linking the effects of rBGH to cancer in humans, they discovered just how dangerous the drug was. Hours before broadcast, the Fox News station cancelled the show after Monsanto threatened “dire consequences”⁹³ if the stories aired.

Pressured by Fox lawyers, Akre and Wilson rewrote the story more than eighty times. After threats of dismissal and offers of six-figure sums to drop their ethical objections and keep quiet, the Florida-based team was fired in December 1997. In 1998, Akre filed a suit against Fox for violating Florida’s Whistleblower Law, which makes it illegal to retaliate against a worker who threatens to reveal employer misconduct. She is the first reporter to ever use the Whistleblower Law against her own employer. The *BHG Bulletin* summarizes: “After a five-week trial and six hours of deliberation that ended in August 2000, a jury awarded Akre \$425,000 in damages, unanimously agreeing that Fox ‘acted intentionally and deliberately to falsify or distort the plaintiffs’ news reporting on BGH.’ In that decision, the jury also found that Jane’s threat to blow the whistle on Fox’s misconduct to the FCC was the sole reason for the termination.”⁹⁴

In February 2004, Fox unexpectedly won an appeal, which withdrew the settlement that had been awarded to Akre. Incredibly, Fox’s lawyers argued that under the protection of the First Amendment, broadcasters had the right to lie on public airwaves! There were no laws, they stated, that forbade a media outlet from distorting the news. The Federal Communications Commission agreed. In 2007, it closed the case—stating that because distorting the news was not against the law, Fox was free to do what it wanted, and therefore Akre’s use of the whistleblower law was invalid.

For a long time after the trial, both Akre and Wilson were blacklisted by the media and could not find jobs—

even though both had won many awards, including four Emmy® Awards (Wilson), and the Associated Press award for investigative reporting (Akre). Eventually, Steve Wilson became chief investigative reporter for WXYZ-TV in Detroit, the most prestigious of ABC affiliate stations. They formed their own production company, and continue to do groundbreaking reporting.

As Jane Akre and Steve Wilson discovered, it takes money and persistence to bring information to the public that is unfavorable to Monsanto. Aware of growing consumer resistance to ingesting unnatural hormones along with their food, Monsanto undertook another approach: lawsuits against dairy companies to prevent them from labeling their products “does not contain rBGH.” After a long fight, the dairy companies (and consumers) won the right to have products that are labeled. However, the victory was only partial. In the United States today, thanks to Monsanto’s close ties with government, products free of rBGH must state that there is no difference between items that contain rBGH and items that do not contain rBGH.

In another clever move, Monsanto decided to rename its product. “Aware that some consumers may be put off by the word *hormone*,” Williams writes, “Monsanto now refers to the drug as supplemental bovine somatotropin or ‘supplemental BST.’”⁹⁵ Monsanto also tried to get a law passed that forbids dairy manufacturers from stating that their milk and milk products are free of supplemental growth hormone. The company’s public relations group claims that informative labels only make consumers unnecessarily afraid. In the meantime, consumers are getting a clear message: it’s okay for the media and corporations to lie.

In its latest clever move, in the summer of 2018 Monsanto merged with Bayer, another huge conglomerate. Probably to improve its deservedly wretched reputation worldwide, the name of Monsanto is now hidden by the merger. To avoid litigation for engaging in illegal antitrust activities, Bayer sold its seed and herbicide business to the German chemical company BASF. However, the intent and activities of Monsanto continue, regardless of what name it currently hides behind.

Aspartame

The food-regulating performance of the Food and Drug Administration is as dismal as its drug-regulating performance. The story of aspartame is worth discussing in depth because it pervades our food supply. Many people use this sweet white powder outright, or eat any number of the 5,000 products in which it appears. The general public believes that aspartame is harmless, and even helpful, because it’s intended as a replacement for cavity-causing sucrose (table sugar). Aspartame has also been promoted as a safe alternative to saccharin, an

artificial sweetener derived from coal tar that not only is carcinogenic, but has recently been discovered to destroy the beneficial flora in the gut. However, aspartame isn’t any safer than what it replaces. Among other hazards, it’s a highly dangerous neurotoxin.

Originally given the brand name NutraSweet®, aspartame has also been marketed under the names Equal®, Spoonful®, Canderel®, Equal-Measure®, Benevia®, Misura®, and AminoSweet®. (The word “amino” suggests naturally occurring amino acids, the

building blocks of protein, in an attempt to bypass consumer fears.) Aspartame was produced by other companies after the patent of its first manufacturer, Searle, expired in 1992.

In July 1974, the FDA delayed approval of aspartame in dry foods due to many independent tests affirming the chemical’s dangers. One study by Dr. John Olney, research psychiatrist from the Washington School of Medicine, revealed holes in the brains of mice after they consumed aspartic acid, a major ingredient in aspartame. In another study, Dr. Harry Waisman, Professor of Pediatrics at the University of Wisconsin, fed aspartame in milk to seven infant monkeys. After 300 days, five of them had *grand mal* seizures and one of them died. Milk tends to mitigate some damage from the chemical, so imagine what might have occurred had the monkeys not been fed milk.

In 1975, an FDA-appointed task force discovered that when Searle had initially submitted research to the FDA, all negative data—including the development of tumors in many of the aspartame-fed animals—was omitted from the report. Searle personnel had simply removed the tumors surgically and reported the animals as healthy

The Fairness Doctrine Is No Longer Fair

The Fairness Doctrine, introduced by the Federal Communications Commission in 1949, required the holders of broadcast licenses to present both sides of a controversial issue—and to do so in an honest and balanced way. Also, to keep their licenses, radio and TV stations had to devote 30 minutes a day to public interest programs. In 1987, the FCC repealed the Fairness Doctrine. Soon after, when news departments were required to generate income, presumably objective reports began to feature “news” about the the same corporations that were pouring millions of advertising dollars into the media.

without checking them for cancer. As a result of these findings, in 1977 a second task force was assigned to investigate the conclusions of the first task force. After this group also charged that Searle had falsified data, the FDA ordered a grand jury investigation of Searle's aspartame studies. Yet during the time the grand jury was active, it did not initiate any legal action against Searle. After the grand jury disbanded, Assistant US Attorney William Conlon, a member of the grand jury, accepted employment with the law firm that represented Searle.

Concurrently in 1977, Searle hired as its CEO former White House Chief of Staff Donald Rumsfeld—and aspartame's status as safe was virtually guaranteed. In January 1981, very soon after Rumsfeld promised a speedy approval, aspartame was indeed approved for use in dry foods by Dr. Arthur Hayes, who had just become FDA Commissioner despite objections by the FDA's own Public Board of Inquiry. In 1983, Hayes approved aspartame for use in diet soft drinks. One month later, Hayes left the FDA—and a few months after that, he began working for the advertising agency that handled NutraSweet®. Hayes joined the firm with a 10-year contract at \$1,000 a day.⁹⁶

Meanwhile, complaints to the FDA about aspartame multiplied. People's symptoms included, but were not limited to: arthritis; autoimmune disorders such as Lupus; burning of the eyes, blurry vision and blindness; digestive disorders, including nausea and vomiting; hearing loss and tinnitus (ringing in the ears); heart problems, including chest pain, palpitations and hypertension; muscle cramping and joint pain; neurological problems, including depression, memory loss, Multiple Sclerosis,

hyperactivity, tremors, seizures, Alzheimer's, slurred speech, headaches, migraines, dizziness, and Parkinson-like symptoms; respiratory problems, including asthma and chronic cough; sexual problems, including infertility, impotence and menstrual problems; tumors of the testicles, breasts and brain; urinary disorders, including burning when urinating; and even coma and death. Not surprisingly, a chemical of this magnitude also creates birth defects in fetuses of pregnant women. This huge range of conditions is due to the ability of aspartame to so thoroughly affect the brain and nervous system. Thus, it can mimic any symptoms and worsen other conditions that are already present.

The new FDA commissioner, ignoring the agency's own register of 10,000 complaints, refused to demand an analysis of the chemical—despite confirmation from respected researchers that after being stored in the refrigerator for only ten weeks, aspartame breaks down and releases formaldehyde and diketopiperazine (known to cause brain tumors). Diet Coke®, a favorite beverage of teenagers, is often stored for that period of time before being consumed.

Then the FDA complaints somehow disappeared entirely. Although the agency had once listed 92 adverse reactions from aspartame—and, in fact, sent a list to all who queried or complained—in 1996, the FDA stopped taking complaints and now denies the report's existence.

By now, enough people had been injured to create a shift. In September 2004, the National Justice League filed charges in a California court against, among other defendants, NutraSweet® Co., the American Diabetes

[The pharmaceutical industry] has moved very far from its original high purpose of discovering and producing useful new drugs. Now primarily a marketing machine to sell drugs of dubious benefit, this industry uses its wealth and power to co-opt every institution that might stand in its way, including the US Congress, the Food and Drug Administration, academic medical centers, and the medical profession itself. . . .

The great majority of "new" drugs are not new at all but merely variations of older drugs already on the market. These are called "me-too" drugs. The idea is to grab a share of an established, lucrative market by producing something very similar to a top-selling drug. . . . Of the 78 drugs approved by the FDA in 2002, only 17 contained new active ingredients, and only 7 of these were classified by the FDA as improvements over older drugs. The other 71 drugs approved that year were variations of old drugs or deemed no better than drugs already on the market. The me-too business is made possible by the fact that the FDA usually approves a drug only if it is better than a placebo. It needn't be better than an older drug already on the market to treat the same condition; in fact, it may be worse. There is no way of knowing, since companies generally do not test their new drugs against older ones for the same conditions at equivalent doses. (For obvious reasons, they would rather not find the answer.)

As their profits skyrocketed during the 1980s and 1990s, so did the political power of drug companies. By 1990, the industry had assumed its present contours as a business with unprecedented control over its own fortunes. For example, if it didn't like something about the FDA, the federal agency that is supposed to regulate the industry, it could change it through direct pressure or through its friends in Congress.

Association, and Monsanto. (Monsanto had purchased G.D. Searle in 1985, and made Searle Pharmaceuticals and NutraSweet® separate subsidiaries.) Among other charges, the manufacturer and the food conglomerates that used the chemical in their products were accused of racketeering, false advertising, and consumer fraud. The court papers disputed the claim that aspartame is safe (including for children and pregnant women). Donald Rumsfeld was also mentioned in the lawsuit.

The arguments used to justify aspartame's presumed safety are insidious. Proponents claim that because two of aspartame's three ingredients, aspartic acid and phenylalanine, are comprised of amino acids, they are "natural" and thus easily handled by the body. But this isn't true. Normal protein foods contain more than just two amino acids. Eight, nine, or twelve amino acids averts the danger of an imbalance—which *does* occur when only one or two amino acids are ingested. The body distinguishes between the two amino acids in aspartame and the many amino acids in milk or a steak. Clearly, as evidenced by the growing number of complaints about aspartame, this synthetic chemical unbalances the system. Moreover, newer research has shown that aspartame is created with a genetically engineered bacterium.

There's also a problem with methanol, the third ingredient in aspartame. The dictionary defines methanol as "a colorless, volatile, inflammable, poisonous liquid, CH₃OH, obtained by the destructive distillation of

wood and used in organic synthesis, as a fuel, and in the manufacture of formaldehyde, smokeless powders, paints, etc."⁹⁷ The only concession that the FDA finally made to consumers is the requirement that foods containing aspartame be labeled for *phenylalanine*, an amino acid that's acknowledged to be dangerous to people with phenylketonuria (a genetic disorder). These individuals lack the enzyme necessary to metabolize phenylalanine, so the amino acid accumulates in the body. At a high enough level, phenylalanine causes severe brain damage.

Although the uproar over aspartame received some media publicity—including Dr. Frank Walton's report on the television show "60 Minutes," which revealed that of 90 independent studies *not funded by the manufacturer*, 83 showed problems with aspartame—this chemical is still on the market, falsely touted by the FDA as safe.

Splenda® (the brand name for sucralose) is a more recent rival of NutraSweet®. Chemically resembling a pesticide, it's also unsafe. Studies show that it causes swelling of the liver and kidneys, and shrinks the thymus gland (a key component of immune function). Also, sucralose reduces the amount of beneficial intestinal flora by 50%.⁹⁸

After the patent on aspartame expired, Monsanto introduced a newer, slightly modified version of the sweetener called neotame. Neotame is 7,000 to 13,000 times sweeter than sugar. Containing more chemicals than aspartame, neotame is even more toxic than its predecessor.

Politics of the Flu

In 2005, then US president George W. Bush predicted that at least 200,000 people in the US alone, possibly up to *two million*, would die from the avian flu. These figures were dutifully reported in the press, despite the fact that up to that point, only 60 deaths from the flu had been reported.

Once panic was induced in the public, people were then given a "solution." They were assured that a medication called Tamiflu® would take care of the problem. But Tamiflu® caused many more problems than it solved. It could only decrease the amount of time one was sick, by less than 17 hours. But that was minor compared to the drug's many other effects: nausea and vomiting, headaches, kidney malfunction, and arrhythmia. But that's not all. It also contributed to psychiatric and neurological disorders—including convulsions, hallucinations, delusions and suicidal behavior—because it was found to interfere with a vital enzyme that the nervous system needs to properly function. There were even reports of deaths in teenagers and children. And ironically, in some cases the drug caused other symptoms that resembled the flu! But apparently this did not matter. The United States government ordered 20 million doses of the drug, with US taxpayers paying the bill. At \$100 per dose, the drug cache cost \$2 billion. Roche, the pharmaceutical company that manufactured Tamiflu®, collected the funds.

But there was another fact that the general public wasn't immediately told. Although Roche collected the money, the drug had been developed by another company called Gilead Sciences, Inc. at least a decade before. What foresight! Around 1995, Gilead sold Roche the exclusive rights to market and sell Tamiflu®. As part of the agreement, Gilead would receive a royalty from Roche equal to about 10% of sales.

By another remarkable coincidence, former Secretary of Defense Donald Rumsfeld was a member of Gilead's board of directors between 1987 and 2001. Rumsfeld was also its chairman from 1997 until 2001, the year he joined George W. Bush's cabinet as Defense Secretary. Although Rumsfeld was no longer serving in an official capacity on Gilead's governing board, he still held stock in Gilead valued at between \$5 million and \$25 million.

HOW DRUGS ARE MARKETED

Standard, common sense language usage indicates that the approval of drugs and the marketing of drugs are two distinctly separate issues. But the cozy relationship between the drug industry and the FDA has merged the two. Billions of dollars a year in advertising help persuade people to take medications. So, let's examine how drugs are marketed.

Corporate-Owned Media

Some readers may like to shop at “mom and pop” businesses—small stores owned by people who live in the neighborhood, and which don't have huge corporations as competitors. A good example is an independent, cozy little coffee shop instead of a Starbucks. Local stores aren't the only businesses forced by mega-corporations to close their doors, though. Once there were privately owned book, newspaper and magazine publishers, as well as independent TV and radio stations.

Today, the word “independent” does not describe major media at all. *A handful of corporations own the media in the United States.* These corporations decide what the public will read, see, watch, and hear. Their intention is to feed us their version of the truth, and have us believe it.

Ben Bagdikian is intimately familiar with the media. In his 1983 book, *The Media Monopoly*, he warned that the 50 corporations that owned the majority of all news media in the US were becoming much too powerful. (“Media” includes all printed and electronic means of information.) Critics laughed at him. In the 4th edition of his book, published just nine years later, Bagdikian pointed out that less than two dozen corporations owned 90% of the mass media. He predicted that eventually this number would drop to about a half dozen companies. By 2000, the publication date of the 6th edition of *The Media Monopoly*, Bagdikian's prediction had proved uncannily prescient: the number of media monopolies had dropped to six. Since 2000, more media mergers have occurred. The expanding media giants now include the Internet market, and there are no signs anytime soon that they will stop trying to control even more public access to information—and hence, the public's consciousness.

In 2004, Bagdikian's (again) revised and expanded *The New Media Monopoly* documented more mergers.

These five [corporations] are not just large, though they are all among the 325 largest corporations in the world . . . [They're] a major factor in changing the politics of the United States and they condition the social values of children and adults alike. These five huge corporations—Time Warner, Disney, Murdoch's News Corporation, Bertelsmann of Germany, and Viacom (formerly CBS)—own most of the newspapers, magazines, books, radio and TV stations, and movie studios of the United States. . . . General Electric's NBC [is] a close sixth.⁹⁹

The dumbing down of America is most evident in the slow decay of substantive content in the enormously influential media, the 30 second sound bites (now down to 10 seconds or less), lowest common denominator programming, credulous presentations on pseudoscience and superstition, but especially a kind of celebration of ignorance.

—Carl Sagan

American astronomer, astrophysicist and author
in *The Demon-Haunted World:
Science as a Candle in the Dark*
(1934–1996)

Bagdikian also discussed the effects of these corporations on popular culture:

They manufacture politics and social values. The media conglomerates . . . have almost single-handedly as a group, in their radio and television dominance, produced a coarse and vulgar culture that celebrates the most demeaning characteristics in the human psyche—greed, deceit, and

cheating as a legitimate way to win (as in the various “reality” shows). . . . [They're also] a major factor in . . . television's increasing crudity and violence because such programs are the cheapest to produce.

These five conglomerates have newspapers and broadcast stations in cities and towns all over the United States, but local people have no voice in what they see and hear, even though, under law, the American public owns the air waves. The five giants fight each other for high ratings in radio and TV, but unseen by the average American, they are quietly corporate partners in joint ventures that make them more like a cartel of interlocked companies.¹⁰⁰

Corporations influence every continent. This is why, decades ago, NBC was able to suppress a news story on the dangers of nuclear power plants. General Electric owns NBC as well as many nuclear plants, and didn't want its stock to fall. Corporate-media marriage also explains why drugs and surgery are pushed, and holistic modalities are ignored, trivialized and slandered. It also explains why most people in the US still haven't heard of Rife Therapy.

Note that six companies own the majority of publications in the science and medical fields.

The Myth of “Peer-Reviewed” Studies

The presumably objective “peer review” process—typical of most scientific journals—is as biased as write-ups from the pharmaceutical companies. In fact, peer review is seriously, *scientifically flawed*. In “Something Rotten at the Core of Science?” the author writes:

A recent US Supreme Court decision and an analysis of the peer review system substantiate complaints about this fundamental aspect of scientific research. Far from filtering out junk science, peer review may be blocking the flow of innovation and corrupting public support of science. . . . [As] most reviewers are likely to be mainstream and broadly supportive of the existing organization of the scientific enterprise, it would not be surprising if the likelihood of support for truly innovative research was considerably less than that provided by chance.¹⁰¹

As the few powerful, wealthy corporations buy smaller companies and make their media empires even larger, the public’s access to the truth becomes even more restricted. This is why I make the effort to seek information from “alternative” sources, both in print publications and on the Internet.

Industry Ties to Medical Journals

An interesting piece, “Scientists Often Mum About Ties to Industry,” appeared in *The New York Times* in 2001.

Scientists who report research findings are expected to divulge any financial ties that might influence their work. But often they do not. . . .

In reviewing 61,134 scholarly articles published in 181 academic journals in 1997, researchers at Tufts University and the University of California at Los Angeles found that just one-half of one percent detailed personal financial interests, including consulting arrangements, honorariums, expert witness fees, company equity and stock, and patents. All of those few disclosures appeared in just a third of the 181 journals. . . . As many as half of all academic researchers consult with industry. . . . Journal editors [says one expert] “are not forceful enough” in requiring disclosure, “or there is widespread disobedience” of their rules.¹⁰²

This conflict-of-interest problem became so serious that in 2000, *The New England Journal of Medicine* apologized to its readers for violating its own rules. It had published

“reviews of the medical literature on drug therapies despite the reviewers’ financial relationships with the companies marketing the drugs.”¹⁰³

Industry-Sponsored, Ghostwritten, and Computer-Generated Articles

Ghostwritten papers from medical school doctors are common. In 2001, drug manufacturer Wyeth-Ayerst hired a company called Excerpta Medica to create a market for its diet drug Redux®. To create this market, Excerpta paid doctors to review and sign articles that were submitted to nine medical journals, without telling the doctors that it (and they) were being funded by Wyeth. Excerpta claimed that the doctors knew about Wyeth’s funding of the supposedly objective articles. But Dr. Richard Atkinson, professor of Medicine and Nutritional Sciences and the director of the Beers-Murphy Clinical Nutrition Center at the University of Wisconsin Madison Medical School—who reviewed and signed one of the Redux® papers—refuted this claim. “If I knew that a drug company had some role, in sponsoring a talk, an article, a symposium, whatever,” he stated, “I think I would be more on my guard to make sure that there was not any bias introduced.” Excerpta Medica did not use the term “ghostwrite.” It said that the authors “facilitate.”¹⁰⁴ Eventually, when Redux® was linked to heart and lung problems, it was pulled from the market and no more promotional articles about it were written.

The Redux® fiasco is a common example of how respected medical journals and otherwise honest doctors become entrapped. Less common—but typical of our electronic age—are computer-generated “studies,” thanks to a program called SCIGen that was invented in 2005 by three graduates of Massachusetts Institute of Technology. Over 200 fake papers from this program were published in journals. In response, a French computer scientist developed a program to analyze whether a study is computer-generated.

Data in Scientific Journals Not Even Correct

Another scandal in the medical and scientific community emerged in the last decade. Large numbers of journal articles were found to be incorrect, and had to be recanted. The authors of these articles did more than “merely” omit data or misrepresent it—they outright invented facts! Most media tried to soften the impact by using euphemisms such as “misleading” and “exaggeration,” but the researchers outright lied. In fact, one article bore the title, “Are scientists lying more than ever?” “The percentage of scientific articles retracted

because of fraud,” it stated, “has increased more than tenfold since 1975.”¹⁰⁵

Rather than focus on infractions by individuals (which can be found in newspaper archives and online), I’ll present an overview. The titles of the reports summarize the problem: “Misconduct accounts for the majority of retracted scientific publications”¹⁰⁶; “Lies, Damned Lies, and Medical Science”¹⁰⁷; and Daniele Fanelli’s 2009 piece, “How many scientists fabricate and falsify research? A systematic review and meta-analysis of survey data,” which examined “behaviours that distort scientific knowledge.” Almost 2% of scientists “admitted to have fabricated, falsified or modified data or results at least once,” while “up to 33.7% admitted other questionable research practices.” When asked to comment on behaviour of colleagues, reports rose to 14.12% for falsification, and “up to 72% for other questionable research practices. . . . [Because] the surveys asked sensitive questions . . . it appears likely that *this is a conservative estimate of the true prevalence of scientific misconduct.* [emphasis added]”¹⁰⁸

Another article, “Why Has the Number of Scientific Retractions Increased?,” explained: “The PubMed database of the National Center for Biotechnology Information was searched on 3 May 2012, using the limits of ‘retracted publication, English language.’ A total of 2,047 articles were identified.” Some of the more serious reasons for retractions were the falsification and complete fabrication of data. The authors defined *falsification* as the “selective manipulation of actual data to present a misleading result,” and *fabrication* as “the manufacture of fictional data.”¹⁰⁹

Back in 2005, a study by Greek epidemiologist John Ioannidis showed that “for most study designs and settings, it is more likely for a research claim to be false than true.”¹¹⁰ His statistical analysis, showing that published data is more than 50% false, is likely more accurate than the findings of Fanelli, who relied on surveys to compile her data. After all, who would willingly expose themselves, even in a survey, for lying? In 2009, Dr. Marcia Angell wrote: “It is simply no longer possible to believe much of the clinical research that is published, or to rely on the judgment of trusted physicians or authoritative medical guidelines. I take no pleasure in this conclusion, which I reached slowly and reluctantly over my two decades as an editor of the *New England Journal of Medicine.*”¹¹¹ In April 2015, medical doctor Richard Horton, editor-in-chief of the respected British journal *Lancet*, bluntly stated:

The very bulk of scientific publications . . . does not deserve to be published at all, and is only published for economic considerations which have nothing to do with the real interests of science.

—John Desmond Bernal
British peace activist, physicist,
and social responsibility advocate
in *The Social Function of Science*, 1939
(1901–1971)

The case against science is straightforward: much of the scientific literature, perhaps half, may simply be untrue. Afflicted by studies with small sample sizes, tiny effects, invalid exploratory analyses, and flagrant conflicts of interest, together with an obsession for pursuing fashionable trends of dubious importance, science has taken a turn towards darkness. As one participant put it, “poor methods get results.” . . . The apparent endemicity of bad research behaviour is alarming. In their quest for telling a compelling story, scientists too often sculpt data to fit their preferred theory of the world. Or they retrofit hypotheses to fit their data. Journal editors deserve their fair share of criticism too. We aid and abet the worst behaviours. . . . Our love of “significance” pollutes the literature with many a statistical fairy-tale.¹¹²

The public (but not the medical community) was shocked by these revelations because scientists have been portrayed as independent of an agenda and dedicated to finding the truth, no matter what the outcome. Why would scientists lie? One reporter summarized the motives:

- ◆ *Profit*: Sometimes there’s money in it—a lot of money. This may be why, according to Fanelli’s report, “surveys conducted among clinical, medical and pharmacological researchers appeared to yield higher rates of misconduct than surveys in other fields.”¹¹³
- ◆ *Laziness and ease of perpetration*: It’s so much easier to just make up data than to perform all those tedious measurements. And in most cases, no one is going to question you about it.
- ◆ *Career pressure*: This is the most common reason. The data isn’t going your way and you may fail to get your thesis accepted, or not get tenure, or miss a promotion, or lose your grant or your job.
- ◆ *Pride*: Scientists are as hungry for praise and prestige as other mortals. And no one likes to be forced to admit he’s wrong. So, when someone contradicts your earlier work, you may be willing to cut a few corners to defend yourself, or to prevent your opponent’s paper from being published.
- ◆ *Ideology*: Many feel that if a cause is worth dying for, it’s worth lying for.¹¹⁴

The Internet Is Co-Opted Too

Many of the world's major medical websites are now owned, either indirectly or directly, by the drug industry. This means that people searching online for medical information—whether they use MedicineNet, WebMD, Medscape or RxList—will not receive accurate information. With huge investments in the drugs they discuss, plus reliance on drug company ads, there's no reason for these websites to be objective or honest.

Publicity Does Not Mean Quality

People in market-driven countries are trained to want more. The media constantly promotes not only products, but now, in this digital age, information as well. We are constantly being told what's important to know and what isn't worth knowing. Often, though, what is easily accessible as "public knowledge" is worthless (and even untrue), while what's hidden is genuinely valuable. I continually hear about serious researchers—often involved in holistic or electromedical therapies that use nutrition and beneficial electromagnetic fields—whose scientifically valid studies, submitted to journals, are rejected because they don't conform to mainstream thinking. This is why many effective lifesaving modalities are never known, or utilized by professionals and the public. The periodicals that claim to report new developments in science actually discourage these reports, because journal advertisers consist of pharmaceutical and medical supply companies—the very businesses that are threatened by innovative, non-drug treatment modalities.

Some scientific journals don't carry huge glossy ads. But this doesn't mean that their publication policies are objective. An editor always tries to match the stories and editorial content to the advertising. If a piece is deemed too controversial, the advertisers take their business elsewhere. Thus the editor is ultimately ruled by finances.

A similar problem exists with funding for scientists, scientific organizations, and universities. They rely on corporations for funding. Even foundations are either directly funded by corporations, or their key personnel have money and other interests tied to corporations.

There's a saying, "Repeat something often enough and people will perceive it as truth." Advertisers count on sheer repetition to sell products. In fact, a decade ago Big Pharma spent over \$60 billion annually on marketing—almost double what it spends on research and development—to ensure that we are not only willing, but eager to ingest their chemicals.¹¹⁵ It's time to stop believing that something is respectable and valid simply because it's constantly repeated.

LEGAL MIND-ALTERING DRUGS

There's a whole other class of drugs that I want to discuss now: legal mind-altering pharmaceuticals, also known as *psychotropic* or *psychoactive* drugs. These drugs, which include tranquilizers, sedatives and antidepressants, affect perception, cognition and behavior. Doctors prescribe psychoactive drugs for both children and adults, but these medications are increasingly being given to the very young. The ostensible reason for administering them is to treat of ADD (Attention Deficit Disorder), ADHA (Attention Deficit Hyperactivity Disorder), dyslexia (characterized by difficulties with reading), various learning disabilities, and hyperactivity. These drugs are very dangerous because they can so radically alter people's behavior. Children and adults do things they ordinarily wouldn't do, such as commit crimes. Since the publication of the 2001 edition of this book, shootings by teenagers, in their homes and in public buildings such as schools, have become grotesquely common. Sometimes the mass murders are followed by the suicides of the killers, and sometimes the person commits suicide without killing others first. Even decades ago, these tragic deaths were linked to prescription psychotropic drugs. Today, the cause-and-effect relationship between the killings and the pharmaceuticals is irrefutable. This relationship has even been occasionally addressed in the mainstream media, although not as consistently or emphatically as it should be.

I will first provide summaries, consisting of the dates and places of the murders, the killers' names, a brief description of their crimes, and then a list of the (legal) drugs they were taking. Then I'll describe the pharmacological effects of many of these drugs; the activism of some parents who want to keep their children sane (but not by medicating them); lawsuits against the drug companies and doctors who insist on drugging the children; and problems in the very diagnoses of these conditions. As you read about the killings, keep in mind that my examples are not a comprehensive list. I have been careful to chronicle *only* those crimes in which the prescribed drugs taken by the killers could be verified. Also, I've done my best to omit the gorier details. My purpose is providing any details at all is to show a pattern: A pharmaceutical is taken; soon after there is markedly changed behavior; then senseless murder occurs (in many cases, of people the killers cared about); and finally, there may be even more drastically altered attitudes in the killers' psyches. These uncharacteristic attitudes range from completely lacking an understanding of what they have done to (in some cases) a total memory blackout

of the murders. Sometimes after the killing sprees, the defendants become themselves again—expressing horror and sincere remorse, and publicly stating that they themselves wish to die for having committed the crimes.

The following drug-related murders, attempted murders, and suicides are listed chronologically from the past to the present. Again, this is only a small sample. Some very informative websites are psychdrugshooters.com, ssristories.org, and thesaveproject.com (from S.A.V.E., an acronym for Stop Antidepressant Violence from Escalating).

Drug-Related Murders

- ◆ In November 1986, 14-year-old Rod Mathews beat a classmate to death with a baseball bat near his home in Canton, Massachusetts. A month before the murder, Rod had written: “My problem is I like to do crazy things. I’ve been lighting fires all over the place. Lately, I’ve been wanting to kill people I hate, and I’ve
- been wanting to light houses on fire. What should I do?”¹¹⁶ Mathews had been taking Ritalin[®] since the third grade.
- ◆ In March 1990, in Portland, Oregon, 16-year-old Courtney Reynolds committed suicide. She had been taking two prescribed antidepressants, Desipramine[®] and Zoloft[®], for six to eight months. According to Ann Tracy, PhD, Executive Director of the International Coalition for Drug Awareness, Courtney was on Prozac[®] at the time of her suicide.
- ◆ In October 1993, in Massachusetts, 15-year-old Gerald McCra, Jr. shot and killed his mother, father, and 11-year-old sister. He’d been taking Ritalin[®] for nine years.
- ◆ In April 1996, 18-year-old Kurt Danysh killed his father with a shotgun. He was taking Prozac[®]. Now, from prison, he writes letters warning that SSRI (Selective Serotonin Reuptake Inhibitor) drugs can kill.

Huge Numbers of Children and Infants Are Being Drugged

When powerful mind-altering drugs are administered to infants and children at a young age, the brain cannot properly develop. The amounts and functions of neurotransmitters (brain chemicals) are changed, the neurotransmitter cell receptor sites are altered, and the brain tissue itself shrinks—of course negatively affecting intelligence and other brain functions. Dr. P. Murali Doraiswamy, professor of psychiatry and medicine at Duke University Medical Center in Durham, North Carolina, cautioned: “Most use in such young children is ‘off label,’ posing safety concerns. For example, a 2013 study of 44,000 children found that antipsychotic drugs tripled the risk for developing diabetes—confirming our warning in 2012 [in the form of a letter to the editor in the *Journal of the American Medical Association*]. . . .”¹¹⁷

The Citizens Commission on Human Rights (cchrint.org) is a nonprofit group dedicated to protecting people from abusive and coercive medical practices, including the act of being forcibly medicated. Below is CCHR’s summary, partly gleaned from IMS Health’s Vector One National and Total Patient Tracker Database for 2013, of how many people are on mind-altering drugs. The numbers of young children and even infants who are given psychotropic drugs is astonishing.¹¹⁸

- ◆ There are 249,669 babies 1 years old and younger who are on anti-anxiety drugs (such as Xanax, Klonopin, and Ativan).
- ◆ There are 26,406 babies 1 years old and younger who are on antidepressants (such as Prozac, Zoloft, and Paxil).
- ◆ There are 1,422 babies 1 years old and younger who are on ADHD drugs (such as Ritalin, Adderall, and Concerta).
- ◆ There are 654 babies 1 years old and younger who are on antipsychotics (such as Risperdal, Seroquel, and Zyprexa).
- ◆ There are 318,997 toddlers age 2 to 3 who are on anti-anxiety drugs.
- ◆ There are 46,102 toddlers age 2 to 3 who are on antidepressants.
- ◆ There are 3,760 toddlers age 2 to 3 who are on antipsychotics.
- ◆ The total number of infants and very young children up to 5 years old who are prescribed psychiatric drugs is 1,080,168.
- ◆ The number of children age 6 to 12 on psychiatric drugs is 4,130,340.
- ◆ The number of children age 13 to 17 years old who are taking psychiatric drugs is 3,617,593.

A deep sense of love and belonging is an irreducible need of all women, men, and children. We are biologically, cognitively, physically, and spiritually wired to love, to be loved, and to belong. When those needs are not met, we don't function as we were meant to. We break. We fall apart. We numb. We ache. We hurt others. We get sick.

Let Go of Who You Think You're Supposed to Be
and Embrace Who You Are* (2010)

- ◆ In May 1997, 18-year-old Jeremy Strohmeyer raped and murdered a 7-year-old girl in a gambling casino in Nevada. Days before the crime, Jeremy was diagnosed with ADHD and prescribed Dexedrine[®]. He tried to commit suicide by taking the 37 Dexedrine[®] pills remaining in the bottle, and left a suicide note expressing his extreme regret and wish to die. (His stomach was pumped and he was sentenced to life in prison.) Jeremy's legal prescription was not mentioned by the FDA at any of the legal hearings, but the *Los Angeles Times* mentioned the drug.
- ◆ In July 1997 in Kansas City, Missouri, 13-year-old Matthew Miller hanged himself in his bedroom closet. He had been taking Zoloft[®] for six days.
- ◆ In October 1997, in Pearl, Mississippi, 16-year-old Luke Woodham stabbed his mother to death. Then he went to his high school and shot nine people, killing two teenagers and wounding seven. He was taking Prozac[®].
- ◆ In December 1997, 14-year-old Michael Carneal shot at students attending a prayer meeting at Heath High School in West Paducah, Kentucky. Three teenagers were killed and five were wounded. Carneal was taking Ritalin[®].
- ◆ Also in December 1997, during a prayer meeting at a high school in West Paducah, Kentucky, 14-year-old Michael Carneal fired a gun that killed three girls and wounded five other students. He was taking Ritalin[®]. According to his friends, at the time of the shooting Michael was very paranoid. He thought that family and friends were plotting against him, and feared that people were hiding in his home's air vents and beneath the floor, waiting to attack him with a saw. He slept with knives under his bed in case of a burglar's attack.
- ◆ In March 1998, in Huntsville, Alabama, 17-year-old Jeffrey Franklin killed his parents with several tools, including a hatchet and a knife. He then wounded three siblings, trying to murder them. Jeffrey was taking Klonopin[®] (an anti-convulsant), Ritalin[®], and Prozac[®], all prescribed by a doctor who had diagnosed him with ADHD and depression. At Jeffrey's trial, a police investigator told the judge that the boy had described hallucinating horns growing from his head.
- ◆ Also in March 1998, at Westside Middle School in unincorporated Craighead County, Arkansas, 11-year-old Andrew Golden and 14-year-old Mitchell Johnson shot and killed one teacher, four students, and wounded ten others. The boys were taking Ritalin[®].
- ◆ In May 1998, in Springfield, Oregon, 15-year-old Kip Kinkel shot his parents while they slept. The next day, at Thurston High School, he shot and killed two classmates and injured over 20 more. This was shortly after he began taking Prozac[®]. He was taking Ritalin[®] after being diagnosed with dyslexia. Police found a note at his home, which he'd written after murdering his parents. The note said, in part: "I have just killed my parents! I don't know what is happening. I love my mom and dad so much. I just got two felonies on my record. [He'd been arrested in school that day, charged with possessing a firearm in a public building and receiving a stolen weapon.] My parents can't take that! It would destroy them. The embarrassment would be too much for them. They couldn't live with themselves. I'm so sorry. I am a horrible son. I wish I had been aborted. I destroy everything I touch. I can't eat. I can't sleep. I didn't deserve them. They were wonderful people. It's not their fault or the fault of any person, organization, or television show. My head just doesn't work right. God damn these voices inside my head. I want to die. I want to be gone. But I have to kill people. I don't know why. I am so sorry! Why did God do this to me. I have never been happy. I wish I was happy. I wish I made my mother proud. I am nothing! I tried so hard to find happiness. But you know me I hate everything. I have no other choice. What have I become? I am so sorry."¹¹⁹
- ◆ In April 1999, in Notus, Idaho, 15-year-old Shawn Cooper brought a shotgun to his high school and held the entire population hostage for about twenty minutes. He fired two rounds, wounding one student. Shawn was taking Ritalin[®].
- ◆ Also in April 1999, at the Columbine school in Littleton, Colorado, 17-year-old Eric Harris and 18-year-old Dylan Klebold killed twelve students and a teacher, and wounded over 20 more people, before killing themselves. Harris had first been taking Zoloft[®], and then Luvox[®]. Klebold's medical records were never publicly released.

- ◆ In May 1999, at Heritage High School in Conyers, Georgia, 15-year-old Thomas (“TJ”) Solomon shot and wounded six students. He was taking Ritalin®. His classmates said that he had a dazed expression on his face; and although normally an accurate marksman with a rifle, he did not kill anyone—and in fact, seemed to be aiming the gun haphazardly.
- ◆ In April 2000, in the state of Iowa, 13-year-old Chris Fetters murdered a favorite aunt with a kitchen knife, and sobbed, holding the woman as she died. Chris was taking Prozac®.
- ◆ In March 2001, in El Cajon, California, 18-year-old Jason Hoffman opened fire at his California high school, wounding five. He was taking two antidepressants, Effexor® and Celexa®.
- ◆ Also in March 2001, 14-year-old Elizabeth Bush shot and wounded an acquaintance at a high school in Williamsport, Pennsylvania. She was taking Paxil® at the time.
- ◆ In April 2001, in Mattawa, Washington, 16-year-old Cory Baadsgaard brought a rifle to Wahluke High School, and held 23 classmates and a teacher hostage. These were friends, he wrote later, whom he had “never once thought about hurting.”¹²⁰ For ten months, up till three weeks before the incident, he had been taking Paxil®, and then switched to a different antidepressant. He stated (and his father confirmed) that he had been feeling suicidal, and had experienced hallucinations and amnesia while on the drugs. He had no memory of the event.
- ◆ In June 2001, 12-year-old Kara Jaye Anne Fuller-Otter (living in an undisclosed United States location) committed suicide. She had been taking Paxil®, and hanged herself while withdrawing from the drug.
- ◆ In November 2001, 12-year-old Christopher Pittman murdered both his grandparents. He was taking Zoloft®. Prior to the murders, his dosage was doubled. He had also been suicidal and experienced other undesirable effects from the medication.
- ◆ In January 2002, 18-year-old Gareth Christian in Vancouver, Canada, committed suicide. He was taking Paxil®. He was beloved in his community and over one thousand people attended his funeral.
- ◆ In July 2002, Billy Willkomm, a student at the University of Florida, was found by his family, hanging from a tall ladder at the family’s Naples, Florida home. He’d been taking Prozac® since the age of 17.
- ◆ In April 2003, near Lafayette, Indiana, Errol Beumel, Jr. (age unknown) shot his father outside the front door of his house. The father fled and collapsed across the road. His son followed him and shot several more times, killing him. Court testimony indicates that Errol Jr. was taking Adderall®. At the criminal trial, his sister testified that she believed her brother was addicted to Adderall®, and that in six months the drug had transformed him from a conscientious and caring individual into a depraved criminal. Also at the trial, two court-appointed psychiatrists testified that Errol Jr. was insane, unable to distinguish between right and wrong at the time of the murder. Dr. Stephen Berger testified that the defendant suffered from a drug-induced psychosis brought on by Adderall®. Errol Jr. testified that spirits convinced him that his father was the devil, and should be killed.
(At the February 10, 2006 hearing, an FDA advisory panel recommended that the pharmaceutical companies include warning labels, inside a black bordered box, for ADHD drugs. The panel also recommended that a medication guide be provided to parents and patients whenever the drugs were prescribed.)
- ◆ In July 2003, in North Wales, Pennsylvania, 17-year-old Julie Woodward hanged herself in her family’s garage. Diagnosed with depression (she had become withdrawn after transferring schools), she had been taking Zoloft® for only one week.

Kara was a beautiful, loving and spirited child. . . . She is now just a “statistic” alongside very many others. . . .

Kara left this Earth on June 7, 2001, while withdrawing from Paxil. She had been taking Paxil for eight months while we continually requested the doctor to discontinue the drug because it seemed as though it was draining the very life right out of her. . . . the damn doctor wouldn’t take her off it, and I asked him to when we went in on the second visit. I told him I thought she was having some sort of reaction to Paxil, but nothing was indicated on the printout sheet that we received with her prescription. . . .

We asked him what would be the worst reaction she would have if she would discontinue the medication. . . . [and] were told flu-like symptoms for 2–3 days. Kara showed signs of what we know now is called akathisia, the last day of her life.

Effects of Some Popular Psychotropic Drugs

This summary does not list: all drugs; all effects; any contraindications; negative reactions if the drugs are taken with other drugs, herbs or foods. *Consult a holistic doctor for a customized natural protocol. And seek medical supervision to wean yourself off these drugs; failure to do so can result in death.*

In some countries, although it's illegal to prescribe these drugs to children under 18 years old, doctors are still permitted to prescribe them "off-label." Read the medicine literature carefully, and research the Internet and the *Physician's Desk Reference*® (available at some libraries).

Most (if not all) of the labels for these drugs warn that because the drugs can cause dizziness, drowsiness or blurred vision, it's unwise to drive, use machinery, or do any activity requiring alertness or clear vision until one's safety is assured. Thanks to decades of demands that these drugs be labeled properly, the labels now indicate that antidepressants have been found to increase the risk of suicidal thoughts and behavior in children, adolescents and adults.

Antidepressants. *Antidepressants typically affect the absorption and location of various neurotransmitters—chemical messengers responsible for mood, mental processes, sensation, motor control, and much more—that are in the brain, nerve cells and even the gut. A chemist may classify antidepressants according to how many rings of atoms they contain (tricyclic or tetracyclic compounds); but the general public is more familiar with the names of antidepressant drugs according to which neurotransmitters are involved. SSRI and SNRI drugs are the most common.*

SSRI, or Selective Serotonin Reuptake Inhibitor Drugs. *Serotonin is a neurotransmitter released by nerve cells and utilized in the brain and the gut. SSRI drugs change the levels of serotonin available to the brain by preventing some of the serotonin normally produced by the body from being reabsorbed back into the nerve cells. SSRI drugs are used for people diagnosed with depression, bulimia nervosa (an eating disorder), obsessive-compulsive disorder (OCD), anxiety and panic disorders, post-traumatic stress disorder (PTSD), and premenstrual dysphoric disorder (PMDD).*

Natural Substitutes: *(a) The amino acid tryptophan (a precursor to serotonin), or 5-hydroxy-tryptophan (the brain chemical into which tryptophan is converted before it's transformed into serotonin). (b) The herb St. John's Wort, which naturally boosts serotonin levels. (c) SAM-e (or s-adenosylmethionine), which helps regulate more than 200 enzymes in the body.*

- ◆ **Fluoxetine (Prozac®, Symbyax®).** *SSRI for diagnosed depression, bulimia, obsessive-compulsive disorder (OCD), panic disorder, and premenstrual dysphoric disorder (PMDD).*

Effects: anxiety; appetite loss; digestive disturbances (nausea); drowsiness; headaches; insomnia; sexual difficulties (problems with orgasm or erection); skin rash, blistering, hives, itching and peeling.

More possible physical effects, for which medical help is advised: shallow or stopped breathing; cancer risk (especially of the breast, in women); fainting; high fever; uneven heartbeat; rigid muscles; nausea and vomiting; restlessness; seizures; severe headache; sweating; weakness.

More possible psychiatric effects, for which medical help is advised: increased depression, hostility, agitation or impulsivity; confusion; hallucinations; memory loss; suicide.

Withdrawal effects: nausea; nervousness; insomnia.

- ◆ **Fluvoxamine Maleate (Faverin®, Fevarin®, Floxyfral®, Luvox®).** *SSRI for diagnosed depression, anxiety, and obsessive-compulsive disorder.*

Effects: digestive disturbances (constipation, diarrhea, nausea, loss of appetite); dizziness; drowsiness; dry mouth; flu-like symptoms; sexual difficulties (problems with orgasm or erection).

More possible physical effects, for which medical help is advised: cancer risk (especially of the breast, in women); shallow or completely stopped breathing; high fever; headache; uneven heartbeat; muscular rigidity; seizures; slurred speech; sweating.

More possible psychiatric effects, for which medical help is advised: agitation; hallucinations; impulsiveness; irritability; panic attacks; racing thoughts; extreme risk-taking behaviors; suicide.

- ◆ **Escitalopram Oxalate (Lexapro®).** *SSRI for diagnosed anxiety in adults and depression in adults and adolescents over the age of 12 years.*

Effects: digestive disturbances (nausea, constipation, gas, upset stomach); dizziness; drowsiness; insomnia; sexual difficulties; dry mouth; weight changes; tinnitus (ringing in the ears).

More possible physical effects, for which medical help is advised: cancer (especially of the breast, in women); shallow or stopped breathing; cancer; severe digestive disturbances (appetite loss, diarrhea, nausea, vomiting); fainting; high fever; headache; uneven heartbeat; rigid muscles; loss of muscle coordination; sweating; seizures.

More possible psychiatric effects, for which medical help is advised: increased aggression, agitation, depression, hostility, impulsiveness, irritability, and restlessness/hyperactivity; suicide.

- ◆ **Paroxetine Hydrochloride (Paxil®).** *SSRI for diagnosed depression, obsessive-compulsive disorder (OCD), panic attacks, anxiety, post-traumatic stress disorder (PTSD), and premenstrual dysphoric disorder (PMDD).*

Effects: concentration difficulties; digestive disturbances (constipation, mild nausea); dizziness; drowsiness; dry mouth; fatigue; insomnia; impaired libido or impotence; memory loss; nasal irritation; nervousness; restlessness.

More possible physical effects, for which medical help is advised: akathisia (inability to remain still); bone bruising and pain; shallow or stopped breathing; cancer risk (especially of the breast, in women); unusually high fever; fast or irregular heartbeat; muscle weakness or spasms; black stools; seizures, shaking or tremors; skin that's bleeding, bruising or peeling, as well as blisters, rash or hives on skin.

More possible psychiatric effects, for which medical help is advised: agitation; anxiety and panic attacks; confusion; heightened depression; hallucinations; excessive hostility, impulsiveness or irritability; abnormal restlessness/hyperactivity; memory loss; seizures; suicide.

- ◆ **Sertraline Hydrochloride (Zoloft®, Lustral®).** *SSRI for diagnosed depression, obsessive compulsive disorder (OCD), panic disorder, post-traumatic stress disorder (PTSD), social anxiety disorder, and premenstrual dysphoric disorder (PMDD).*

Effects: appetite changes; digestive disturbances (constipation, diarrhea, nausea, stomach pain); dizziness; drowsiness; dry mouth; headache; insomnia; menstrual irregularities (for females); nervousness; sexual difficulties (inability to ejaculate for males, orgasm difficulties for females, impotence, decreased libido); weight loss.

More possible physical effects, for which medical help is advised: akathisia (inability to sit still); breathing difficulties; loss of bladder control; breast tenderness or enlargement, or unusual secretion of milk (in females); cancer risk (especially of the breast, in women); convulsions and tremors; fainting; fast or uneven heartbeats; high fever; muscle cramps, rigidity, stiffness or twitching; stuffy nose, runny nose or nosebleeds; overactive reflexes; skin rash, hives, itching, burning, numbness, prickling, tingling, or red or purple spots; shivering; sweating; swelling (especially of the face, tongue or throat); increased thirst; cloudy urine.

More possible psychiatric effects, for which medical help is advised: agitation; aggressiveness; anxiety; concentration difficulties; increased depression; hallucinations; hostility; impulsiveness; irritability; panic attacks; restlessness; any feelings or actions that seem out of control; vision changes; suicide.

Special warnings: If this drug is discontinued abruptly, withdrawal effects include abdominal cramps, fatigue, flu-like symptoms, and memory impairment.

- ◆ **Other related Antidepressant SSRI Drugs:** *Citalopram Hydrobromide (Celexa®, Cipramil®), Chlorprothixene (Taractan®, Truxal®, Tarnin®), Imipramine Hydrochloride (Tofranil®), Vilazodone (Viibryd®)*

SNRI, or Selective Norepinephrine Reuptake Inhibitor Drugs. *Similar to SSRI drugs, SNRI drugs inhibit the brain's reabsorption of not only serotonin, but also of norepinephrine. Medical literature states that this class of drugs is not used as often as SSRI pharmaceuticals because they have even more side effects than the SSRIs. For diagnosed depression, psychosis, schizophrenia, and bipolar disorder (manic-depression).*

Natural Substitutes: **CAUTION!** *According to Julia Ross, people suffering from bipolar disorder (manic-depression) should not use L-glutamine, L-tyrosine, SAM-e or St. John's Wort, or consume high doses of fish oil, flax oil or chromium, without consulting a skilled psychiatrist or psychopharmacologist. (a) Similar supplements as are given to those who would otherwise be on SSRI Drugs (see first page of this Insert), but heed the CAUTION statement at the beginning of this paragraph. Always consult a holistic physician for customized protocol. (b) Folate, whose deficiency is involved in schizophrenia. Methylfolate—also known as methyltetrahydrofolate or 5-methyltetrahydrofolate—is the most bioavailable form of folate. It's possible that a high percentage of people diagnosed with schizophrenia cannot convert either the folate that naturally exists in foods, or the poisonous synthetic folic acid that's put into many vitamin supplements, into the bioavailable methylfolate. (c) All the B Vitamins.*

- ◆ **Venlafaxine Hydrochloride Extended Release (Effexor ER®).** *SNRI (serotonin and norepinephrine reuptake inhibitor) for diagnosed depression.*

Effects: digestive disturbances (appetite loss, constipation, diarrhea, mild nausea, stomach pain, vomiting); abnormal dreams; dizziness; drowsiness; dry mouth; fatigue; headache; insomnia; nervousness.

More possible physical effects, for which medical help is advised: breathing difficulties; tightness or pains in chest; fast or irregular heartbeat; decreased physical coordination; impaired libido and impotence; peeling skin, or blisters, rash or hives on skin; black or bloody stools; swelling of face, lips, tongue, or throat; tinnitus (ringing in ears).

More possible psychiatric effects, for which medical help is advised: agitation; anxiety and panic attacks; confusion; heightened depression; hallucinations; excessive hostility, impulsiveness or irritability; abnormal restlessness/hyperactivity; memory loss; seizures; suicide.

- ◆ **Mirtazapine (Remeron®).** *SNRI (serotonin and norepinephrine reuptake inhibitor) for diagnosed depression as well as nausea, anxiety, post-traumatic stress disorder (PTSD), and to stimulate appetite.*

Effects: appetite increase; digestive disturbances (nausea); dizziness; sleepiness; weight gain.

More possible physical effects, for which medical help is advised: shallow or completely stopped breathing; loss of coordination; flu-like symptoms; uneven heartbeat; high fever; rigid muscles; sweating; white patches and sores in mouth and on lips.

More possible psychiatric effects, for which medical help is advised: agitation; trouble concentrating; increased depression; hallucinations; memory loss; suicide.

- ◆ **Other related Antidepressant SNRI Drugs:** *Duloxetine (Cymbalta®), Trazodone Hydrochloride (Desyrel®), Venlafaxine (Effexor®)*

- ◆ **Other related Antidepressant Drug:** *Bupropion Hydrochloride (Wellbutrin®), which blocks the reabsorption of the neurotransmitters norepinephrine and dopamine (which, along with adrenaline, are produced by the body using the amino acid tyrosine as one of the main raw ingredients)*

Tranquilizer Drugs (Benzodiazepines). *A tranquilizer (which is often a drug in the benzodiazepine family) binds to receptor sites of the neurotransmitter GABA (gamma-aminobutyric acid). GABA, which is naturally produced by the body, calms and suppresses the activity of nerves. Some people are deficient in GABA. The medical community states that it does not know exactly how benzodiazepine drugs work. Chiefly used for people diagnosed with anxiety, tranquilizers are also used for panic attacks, depression, insomnia, and seizures.*

Natural Substitutes in Supplement Form: *(a) The amino acid GABA, which is a potent mood enhancer. (b) The amino acid taurine, which acts similarly to GABA. (c) The amino acid glycine, which acts similarly to GABA. (c) The herbs hops, lemon balm, passionflower, skullcap, and valerian (among others), which have calming effects on the nervous system. However, the drug manufacturers suggest avoiding these herbs when the person is taking the drug. (d) Melatonin, a natural hormone produced by the pineal gland that regulates sleep, has proven helpful for people who are stopping the Benzodiazepine drugs. (e) The herb kava has been shown, in at least one clinical trial, to be helpful in alleviating withdrawal symptoms from people who are stopping the Benzodiazepine drugs.*

- ◆ **Alprazolam (Xanax®, Niravam®).** *Benzodiazepine for diagnosed anxiety and panic attacks.*

Effects: balance and coordination problems; impaired concentration; digestive disturbances (constipation, diarrhea, nausea, vomiting); dizziness; drowsiness; dry mouth; fatigue; insomnia; irritability; impaired libido or impotence; stuffy nose; nervousness; restlessness; skin rash; slurred speech; swelling in hands and feet; blurred vision.

More possible physical effects, for which medical help is advised: fainting; chest pain, or fast/irregular heartbeat; jaundice; seizures and convulsions; swelling of lips, tongue, throat or face; urinating less or not at all.

More possible psychiatric effects, for which medical help is advised: agitation; depression; hallucinations; hostility; hyperactivity; unusual risk-taking behavior and decreased inhibitions (inability to accurately discern real danger); suicide.

Withdrawal effects: increased anxiety; depression; depersonalization; headache; muscle pain; insomnia; shakiness, tremors and twitching; hypersensitivity to touch.

- ◆ **Lorazepam (Ativan®).** *Benzodiazepine for diagnosed anxiety, panic attacks, depression, insomnia, and alcohol withdrawal.*

Effects: balance and coordination problems; digestive disturbances (constipation, nausea, vomiting); dizziness; drowsiness; dry mouth; chills; bleeding gums; headache; insomnia; impaired libido or impotence; skin rash; weakness; unusual weight gain; blurred vision.

More possible physical effects, for which medical help is advised: shallow or stopped breathing; convulsions and seizures; fainting; fever; fast or irregular heartbeat; itching and swelling of face, tongue and throat; slurred speech; sweating; black stool; unsteady walk; weakness.

More possible psychiatric effects, for which medical help is advised: agitation; confusion; depression; hallucinations; hostility; hyperactivity; memory loss; increased irritability nervousness, restlessness; suicidal thoughts and behavior.

Withdrawal effects: agitation; insomnia; seizures and tremors; sweating; vomiting.

- ◆ **Other Related Tranquilizer Drugs:** *Clobazam (Onfi®), Clorazepate Dipotassium (Gen-XENE®, Tranxene®), Chlordiazepoxide Hydrochloride (Librium®, Limbitrol®, Lipoxide®, Mitran®, Reposans-10®, Sereen®), Clonazepam (Klonopin®), Diazepam (Diastat®, Valium®, Valrelease®, Vazepam®), Estazolam (Prosom®), Fluphenazine (Duraclon®), Flurazepam Hydrochloride (Dalmane®, Durapam®), Halazepam (Paxipam®), Lithium (Eskalith®, only somewhat related but considered a tranquilizer), Mesoridazine (Serentil®), Midazolam (Versed®), Oxazepam (Serax®), Perphenazine (Etrafon®, Trilafon®), Prochlorperazine (Compazine®), Promazine (Anectine®), Quazepam (Doral®), Temazepam (Razepam®, Restoril®, Temaz®), Thioridazine (Mellaril®), Triazolam (Halcion®), Triflupromazine (Robinul®)*

Stimulant Drugs (Methylphenidates, Amphetamines, Dextroamphetamines, and Methamphetamines). *Stimulants affect the central nervous system and brain by increasing the levels of the neurotransmitter dopamine. They also increase heart rate and blood pressure, and suppress appetite. The medical community says it doesn't know how amphetamine drugs calm hyperactive people. Used for children and adults diagnosed with Attention Deficit Hyperactivity Disorder (ADHD) and narcolepsy (falling asleep easily at any time, due to the brain's failure to regulate normal sleep-wake cycles). Off-label, used for depression, obesity, and nasal congestion.*
Natural Substitutes in Supplement Form: *Amino acid L-tyrosine, with L-glutamine and GABA; calcium and magnesium; Vitamin B6 (administered with B Complex); sometimes bacopa (herb).*

- ◆ **Methylphenidate Hydrochloride (Ritalin®).** *Stimulant chemically related to amphetamines. Widely used for diagnosed Attention Deficit Hyperactivity Disorder (ADHD) in children and adults, as well as narcolepsy (inability to remain awake during the day due to a malfunction in the brain).*

Effects: addiction, often to cocaine; appetite loss; shortness of breath; confusion; convulsions; chest pain; depersonalization (feelings that the person and their environment is not real); digestive disturbances (abdominal or stomach pain, decreased appetite, nausea); dizziness; fast or irregular heartbeat; fever; headache; insomnia; joint pain; memory loss; muscle cramps; stuffy nose; nervousness, agitation, anxiety and irritability; seizures in those with a history of seizures; skin flaking and scaling, hives, rash, redness, or unusual warmth; vocal or physical tics (uncontrolled, repeated body movements); blurred vision.

More possible physical effects, for which medical help is advised: cancer risk; painful, constant penile erection lasting more than four hours (which, if not treated immediately, can lead to scarring and permanent erectile dysfunction in the male—effects on females not documented); high blood pressure; hyperthyroidism (overactive thyroid); overactive reflexes; extreme restlessness; tremors; sweating; swelling of hands, feet or ankles; urinary tract and other infections; vomiting; reduced blood flow to the brain, which can lead to stroke.

More possible psychiatric effects, for which medical help is advised: aggression; depression; delusions; hallucinations; panic; paranoia and suspicion; psychosis that appears to be schizophrenia; severe psychological dependence on the drug itself; suicide.

Other data: Often, children given this drug experience slowed growth, as it can disrupt the development of brain cells in the hippocampus of the brain—the region responsible for memory, spatial navigation, and appropriate behaviors. Severe dependence on this drug is probable (similar in its effects to cocaine), which means that it should not be withdrawn abruptly.

- ◆ **Other Methylphenidate Drugs:** *Concerta®, Daytrana®, Focalin®, Metadate®, Methylin®, Quillivant®*

- ◆ **Amphetamine plus Dextroamphetamine Salts (Adderall®).** *Stimulant used for diagnosed Attention Deficit Hyperactivity Disorder (ADHA) in children and adults, and narcolepsy.*

Effects: agitation, anxiety and fear; unusual excitability and irritability; high blood pressure; digestive disturbances (constipation, diarrhea, stomach pain, nausea, vomiting); dizziness; dry mouth; hair loss; headache; increased heart rate and heart palpitations; insomnia; impaired libido and impotence; nervousness; numbness; restlessness; teeth grinding; tremor; blurred vision; weakness; weight loss.

More possible physical effects, for which medical help is advised: breathing or swallowing difficulties; cardiac arrest; emotional extremes (whether happy or sad); motor tics and muscle twitches; pain when urinating; seizures; stroke.

More possible psychiatric effects, for which medical help is advised: addiction; aggressive and hostile behavior; delusions; depression; hallucinations; severe mood swings (bipolar disorder); psychosis.

Other data: Adderall® is habit forming. Chronic use may lead to dependence or sudden death.

- ◆ **Other Amphetamine Drugs:** *Desoxyn®, DestroStat®, Dexedrine®, Lisdexamfetamine (Vyvanse®), ProCentra®*

Antipsychotic or Neuroleptic Drugs (Phenothazines). *Used for diagnosed psychosis, schizophrenia, bipolar disorder (the manic aspect of manic-depression), occasionally depression, and Tourette's syndrome (excessive movements and verbal tics). Doctors believe that these drugs tranquilize the brain by blocking transmissions that utilize the energizing neurotransmitter dopamine. The drugs bind to the dopamine receptor site and usually depress the nervous system; but sometimes they cause restlessness and akathisia (the inability to remain still). Phenothazine was first introduced by DuPont in 1935 as an insecticide. Pharmacologically, Phenothazine is further divided into three sub-groups; but for the purposes of this Insert all types are grouped together.*

Natural Substitutes: *Foods high in Omega 3 fatty acids, such as wild salmon, cod liver oil and grass fed beef). Specialized supplementation: includes amino acids glycine and sarcosine; zinc; magnesium; and antioxidants (Vitamins C and E, and Alpha Lipoic Acid), which help repair damage caused by long-term use of neuroleptic drugs. Holistic doctors also remove gluten from the diet.*

- ◆ **Chlorpromazine Hydrochloride (Thorazine®, Largactil®, Megaphen®, Promapar®).** *Used to treat diagnosed schizophrenia, psychotic disorders, the manic phase of bipolar disorder, manic-depression, and perceived severe behavior problems in children age 1 through 12.*

Effects: low or irregular blood pressure; breast swelling or discharge; digestive disturbances (abdominal or stomach pain, constipation, nausea and vomiting); dizziness; drowsiness; dry mouth; headache; heart palpitations; nasal congestion; neck spasms; sexual difficulties (problems with orgasm or erection); blurred vision.

More possible physical effects, for which medical help is advised: balance problems; breathing difficulties; high fever; insomnia; jaundice (yellowing of the skin or eyes); joint pain; mouth sores and swollen gums; muscle twitching and other uncontrolled movements; muscle rigidity; skin bleeding or bruising; difficulty swallowing; tremors and fainting; weight gain.

More possible psychiatric effects, for which medical help is advised: agitation and restlessness; confusion; unusual thoughts or behaviors; increased deaths in elderly persons diagnosed with dementia-related psychosis.

- ◆ **Haloperidol (Haldol®).** *Used to treat diagnosed schizophrenia, psychotic disorders and the manic aspect of manic-depressive disorder, to control perceived behavior problems in children, and to manage excessive motor movements and verbal tics (as in Tourette's syndrome). This drug is about fifty times stronger than Chlorpromazine (see above). Haloperidol is in its own group but also contains Phenothazine, so is included here.*

Effects: anxiety and restlessness; breast enlargement; confusion; digestive disturbances (constipation, diarrhea, nausea and vomiting); drowsiness; dry mouth; headache; insomnia; rigid muscles or uncontrolled movements and twitching of limbs and face; sexual difficulties; speech problems; difficulty urinating; blurred vision.

More possible physical effects, for which medical help is advised: balance problems, dizziness or sensation of spinning; breathing difficulties; cancer risk; chest pain; cough with yellow or green mucus; fainting; swollen gums or mouth sores; erratic or pounding heartbeat; high fever; insomnia; jaundice (yellowing in eyes or skin); joint pain; mouth sores and swollen gums; muscle twitching and other uncontrolled movements; muscle rigidity; skin bleeding, bruising, itching or rash; neck or throat spasms; difficulty swallowing; tremors, fainting and seizures; weight gain. Unexpected deaths.

More possible psychiatric effects, for which medical help is advised: agitation; hallucinations.

- ◆ **Other Phenothazine and Related Drugs:** *Acetophenazine (Tindal®), Amitriptyline Hydrochloride (Estrafon®), Aripiprazole (Abilify®), Clozapine (Clopine®, Clozari®, Denzapine®, FazaClo®, Synthron®, Versacloz®, Zaponex®), Fluphenazine Hydrochloride (Permitil®, Prolixin®), Loxapine (Loxitane®), Mesoridazine (Serentil®), Olanzapine (Lanzek®, Zypadhera®, Zyprexa®), Perphenazine Hydrochloride (Trilafon®), Prochlorperazine (Compazine®, Compro®, Procomp®), Promazine (Sparine), Quetiapine (Seroquel®), Risperidone (Risperdal®), Thioridazine Hydrochloride (Mellaril®), Trifluoperazine Hydrochloride (Stelazine®), Ziprasidone (Geodon®)*

Breathing is a pulsation in which expansion and contraction of the body alternate. The simplest way to block the expansive or contractive movement of the body in emotional expression is to suspend the main pulsation in the organism: to hold the breath. Not that this is a conscious process. The jaw clamps shut, or the muscles of chest and abdomen spontaneously tighten as anxiety is felt.

The word *anxiety*, from the Latin word for "narrow," expresses this experience of tightness of the muscles of jaw, throat, chest, and abdomen. The channel of breathing is narrowed. Anxiety in its most intense form is fear—a total contraction of the organism. But normally anxiety is a partial contraction against an impending movement of emotion.

When the expansive emotions of joy or rage are blocked, either chronically or in a temporary emergency, the breathing tends to block in a deflated position, with the body area contracted. A depressed person, whose organism resists either joy or rage, tends to be stuck in an attitude of deflation. The body is slumped, hunched, folded forward. The attitude seems to say "I've given up."

When the contractive emotions of grief or fear are blocked, the breathing tends to be held in an inflated position, the chest puffed out. The attitude may seem defiant: "I won't give in."

- ◆ In October 2013, in Sparks, Nevada, 12-year-old Jose Reyes opened fire at Sparks Middle School, killing a teacher and wounding two students before committing suicide. He was taking fluoxetine (a generic version of Prozac[®]), prescribed by a psychiatrist, at the time.
- ◆ In April 2014, in Milford, Connecticut, 16-year-old Chris Plaskon stabbed a friend to death at Jonathan Law High School after she declined his invitation to the prom. At the trial, Chris's attorney stated that his client had been diagnosed with ADHD and was taking prescribed medications for psychosis and anxiety. The boy said that demons had told him to kill the girl.

Not all drug-related murders, attempted murders, and suicides have been committed by children or teenagers. Young adults in their 20s, and older adults with children, have also been affected by these drugs. For example:

- ◆ In January 1999, in Grand Forks, North Dakota, Ron Ehlis killed his 5-week-old daughter ten days after he started taking Adderall[®]. As a child, Ron had been diagnosed with ADD and was prescribed Ritalin[®]. When he was 26 years old, a psychiatrist he consulted (because he was having a hard time with his college studies) prescribed Adderall[®], but did not perform any tests first. Following the doctor's instructions, Ehlis doubled the dose after a few days, after which he began suffering from hallucinations and delusions. He shot his baby girl, believing that he was following orders from God. Then he shot himself in the stomach. Ron was charged with murder, but the charges were later dismissed after several doctors testified that he was suffering from a psychotic disorder induced by amphetamines. The mother of the child he had killed testified that Ron had not been behaving normally from the moment he started taking the Adderall[®].
- ◆ In September 1999, in Spokane, Washington, Sharon Curry stabbed and killed her 8-year-old daughter before stabbing herself. On Adderall[®] at the time, Curry was found not guilty of all charges. Doctors for both the defense and the state agreed that Sharon suffered from a drug-induced insanity that caused such an aberrant mental state, she was unable to distinguish between right and wrong. Sharon sued her doctor for prescribing an excessive dose of Adderall[®], which had caused her to kill her daughter. The lawsuit was settled out of court, its details withheld from the public.

- ◆ In March 2000, in Scottsdale, Arizona, Dawn Branson was driving with her son in the car when she suffered a psychotic episode. Court documents stated that Dawn heard a voice saying: “Let go of the steering wheel and gas. God will drive the car. Don’t you trust him?”¹²¹ So Branson released the wheel, resulting in a car accident that caused her serious injuries and killed her son. Dawn Branson was taking (prescribed) Adderall® at the time. Prior to taking the drug, she’d never had a psychotic episode. After she stopped taking the drug, her psychotic episodes ceased.
- ◆ In February 2008, in a Northern Illinois University auditorium in DeKalb, Illinois, 27-year-old Steven Kazmierczak shot and killed five people, wounded 21 others, and then killed himself. According to his girlfriend, he had recently been taking Prozac®, Xanax® and Ambien®. Post-mortem toxicology results revealed trace amounts of Xanax® in his system.
- ◆ In June 2014, in Seattle, Washington, 26-year-old Aaron Ybarra opened fire at Seattle Pacific University, killing one student and wounding two others. He had reported, in 2012, that his psychiatrist had prescribed Prozac® and Risperdal®.
- ◆ In November 2014, in Tallahassee, Florida, 31-year-old Myron May opened fire in the library of Florida State University. He wounded three people before he was shot and killed by police. After the incident, May’s friends stated that he had been prescribed Wellbutrin® and Vyvanse®. Around the same time, they had found Seroquel® among his prescriptions as well. ABC Action News also reported a prescription for Hydroxyzine® (an anti-anxiety drug) in his apartment. Two months before the murders, May had been admitted to a local mental health center, Mesilla Valley Hospital.

So far, all of the murders summarized here happened on the ground. A later event—which to many, felt even more shocking because of the venue and the number of people killed—occurred in a plane en route from Spain to Germany in March 2015. The co-pilot, 27-year-old Andreas Lubitz, deliberately crashed the plane once it was in mid-air. Everyone on board (150 people), including Lubitz, was killed. Diagnosed with depression, anxiety and panic attacks, Lubitz had been taking Lorazepam® and other medications. With rare exceptions, the US Federal Aviation Administration does not allow pilots to use mind-altering drugs (such as Lorazepam®) that interfere with the ability to operate vehicles on the road or in the air.

The Pharmacology of Psychotropic Drugs and the Battle for Disclosure

A Brief Summary of the Brain

It can be very difficult to believe that people taking prescription psychotropic drugs can become so deranged, so different from how they would normally behave, that they would kill other people. The apparent formula of cause and effect does seem simplistic: child takes drug and murders, or child takes drug and commits suicide, or both. How could mind-altering drugs “alter the mind” so much that they turn someone into a criminal?

The Insert on page 56, “Effects of Some Popular Psychotropic Drugs,” summarizes the effects on mind and body from different types of mind-altering drugs. But in order to understand *why* they exert these effects, we need to learn first how brain chemicals work. Just a brief summary will suffice.

The body contains four classes of chemical messengers called *neurotransmitters*. *Neuro* designates “neuron,” which is a nerve cell. And *transmitter* means just that: the transportation, or transmission, of a biochemical from cell to cell. Neurotransmitters dictate how we conduct ourselves in the world and they cover an enormous range of functions: mood, mental acuity, perception, sensation, temperature control, motor coordination, digestion, sleep, blood pressure, aggression levels, and more. The Insert on page 65, “Functions and Effects of Neurotransmitters,” summarizes the four basic neurotransmitters (or neurotransmitter groups) and their impact on us if their levels are adequate or unbalanced on the low side.

Neurotransmitters at higher than average levels are not discussed, but you can get a sense of what those effects might be by exaggerating the benefits. For instance, dopamine and other catecholamines are *endogenous*—that is, naturally produced by the body—amphetamines. If, at normal levels, the catecholamine group promotes energy and focus, excessively high levels could induce someone to be excessively energized and hyper-focused or obsessive, resulting in compulsive, risk-taking behaviors.

Our neurochemicals are interconnected with the world around us. Just as our neurochemical levels affect how we feel, perceive and respond to our environment, the environment affects our neurotransmitter levels. There will always be fluctuations in neurotransmitter levels, depending on diet, amounts of exercise and sleep, relationship satisfaction, work stressors, and so on; after all, humans aren’t static machines. Sometimes, though, the amounts of neurochemicals being secreted are adequate but the timing is off. For example, there might be a shortage of catecholamines in the morning, which is

when greater amounts are needed for activity; and there might be a surge in these biochemicals at night, which is when the body should be producing less in order to relax for sleep. Some people naturally possess greater or lesser levels than others, but there's a preferred range, and ideally our levels should fall within that range. When the levels do not, our quality of life suffers, often dramatically.

The neurotransmitter I want to discuss in some depth is serotonin, because so many murders are perpetrated by people who are taking the class of drugs called SSRIs (Selective Serotonin Reuptake Inhibitors). Once you understand how SSRIs affect the brain, you can apply these general principles to other types of psychotropic drugs.

Serotonin is a very important neurochemical. It helps us feel mellow and calmer, decreases pain, and acts as an antidepressant and sleep aid. There is no "typical" serotonin level (which is determined by a blood test) because these levels are constantly fluctuating, due to diet and other factors. Serotonin can be made only by our bodies. It's created from the amino acid tryptophan, along with certain vitamins and minerals.

Like other neurotransmitters, serotonin delivers its biochemical messages by traveling from one neuron to another. Once it's released—that is, *fired*—by a nerve cell, receptors on adjacent nerve cells are activated. The serotonin is then reabsorbed back into the neuron via a process called *reuptake*. The body reactivates the serotonin transmitter for further use, the serotonin fires again, and this cycle repeats innumerable times.

This naturally occurring cycle gets interrupted once an SSRI drug is in the system. The drug blocks the receptor sites, there is no reuptake or reabsorption of serotonin, and no serotonin can be discharged for further use. The rationale for deliberately aborting this function is that with less (or no) reuptake of serotonin back into the nerve cells, more serotonin is available to the brain. But this reasoning is flawed. Once the receptor sites are no longer used, the body deactivates them. Why keep an establishment open for business if there are no customers?

Plenty of research in mainstream medical sources confirms that if this downward spiral continues, most of the receptor sites stop working. One study, published in 2002 in *The Journal of Neuroscience*, showed that it took only fifteen days for an SSRI drug to deactivate 80% of the body's serotonin receptor sites.¹²² The medical community even has a term for the loss of function of serotonin receptor sites: *downregulation*. But this is a misleading term. It doesn't even begin to adequately describe what's really happening: *the desensitization and eventual deterioration of serotonin receptor sites*. People on SSRI antidepressants not only gradually lose their

serotonin receptor site function, but they also lose the benefits that serotonin provides.

This is why there are so many seemingly disparate "side" effects of SSRI drugs. Perhaps if people understood that these drugs cause the body to lose its ability to function normally, they might not choose to take them.

Using a dangerous drug to try to trick the body into "finding" more serotonin than is actually present is a ruse that ultimately backfires. It makes far more sense to provide the body with what it needs so that it can manufacture more of the neurotransmitter. The amino acid tryptophan (or a molecular variant, 5-hydroxy-L-tryptophan) is the only substance that can create serotonin. Foods that contain lots of tryptophan include free range turkey, wild fish, grass fed beef, whey, pastured eggs, and nuts. A small amount of complex carbohydrate eaten with the protein helps clear all of the amino acids except tryptophan from the bloodstream. This allows tryptophan to cross the blood brain barrier, unimpeded, and form serotonin. Some of the best carbohydrates for this task include bananas, sour cherries, and buckwheat. One food that contains both tryptophan and carbohydrates—along with scores of other phytochemicals that the brain loves—is cacao. Not surprisingly, many depressed people feel better after eating just a few ounces of chocolate.

It has taken many deaths to help make the public even start being aware of the dangers of psychotropic drugs. It's important to know that emotional and mental issues can be managed with natural methods. However, balancing brain chemicals is complex, and requires knowledge, skill, experience, and suitable raw materials. Fortunately, there are dedicated natural health professionals who can help.

Uncovering the Data

Today, anyone with an Internet connection can obtain information about "side" effects of psychotropic and other drugs—along with *contraindications*, or medical reasons why people with certain conditions shouldn't take them at all. Although the websites refer consumers to their doctors for more data, at least some of the dangers are revealed (despite the manufacturers' assertions that many of the reported negative reactions are "rare"). Note that all of the information about the effects of psychotropic drugs, cited in the lengthy Insert on the previous pages, was compiled from medical websites.

While ready access to such information might seem routine to us today, the average consumer didn't always have it. The pharmaceutical companies weren't even this transparent. It took decades of radically altered behavior, psychological breakdowns, murders, suicides, ruined lives and lawsuits, before consumers were granted access to

FUNCTIONS AND EFFECTS OF NEUROTRANSMITTERS			
Neurotransmitter	Indicators of Proper Levels	Indicators of Abnormal Levels	Substances that Help Produce Neurotransmitter
<i>Catecholamines</i> This group includes dopamine (some of whose pathways are in the frontal lobe of the brain), as well as two related biochemicals made from dopamine: norepinephrine (sometimes called noradrenaline) and adrenaline (sometimes called epinephrine). The two related biochemicals are produced and regulated by the adrenal glands.	Energized, alert, focused, purposeful, interested in environment. One is able to plan and set goals. Dopamine is a natural, gentle amphetamine that monitors metabolism, controls blood pressure and digestion, and generates electricity for voluntary movements.	Apathy, distractability, indecision, depression, fatigue, hopelessness, obesity, sleeplessness, addictiveness, loss of muscular control. Cravings for stimulants (such as caffeine and "recreational" drugs) and sugar. Deficiency personality: loner, procrastinator.	Amino acids L-tyrosine and D-phenylalanine, abundant in animal proteins. Taken as a powder by mouth with L-glutamine powder (another amino acid), L-tyrosine stabilizes moods. D-phenylalanine creates endorphins that eliminate pain and addictions. Don't take these energizing supplements before bed.
<i>Acetylcholine</i> A lubricant and neuromodulator produced in the parietal lobe or "thought center" of the brain, it keeps internal structures moist and adjusts how the brain processes information. Acetylcholine maintains the signaling capacity and structural integrity of cell membranes. It also builds myelin, the insulation around neurons that prevents an electrical signal from dissipating as it passes through a neuron.	Positive, confident, easygoing, flexible and creative, with good problem solving ability, enhanced verbal processing, fast reactions, and strong focus. This neurotransmitter helps maintain short-term memory, enhances communication between brain cells, improves digestion, and maintains steady heartbeat.	Negative, obsessive, worried, irritable, quarrelsome, memory loss, language confusion. Sleeplessness, headaches, decreased mental energy ("brain fog"), learning and cognitive disabilities (senile dementia, Alzheimer's). Deficiency personality: perfectionist, eccentric.	Foods rich in choline build acetylcholine: egg yolks, organ meats such as liver, raw dairy, broccoli, Brussels sprouts, quinoa, amaranth, and raw cacao. Available as a supplement (in the form of phosphatidylserine), acetylcholine can be taken with dimethylaminoethanol (DMAE), to penetrate cell membranes more easily.
<i>GABA, gamma-aminobutyric acid</i> This amino acid is made by brain cells from the amino acid precursor glutamate. Glutamate excites nerve impulses, while GABA prevents them from firing too easily. A natural tranquilizer, GABA produces endorphins (natural painkillers made by the body). GABA is active in the brain's temporal lobe, which governs memory and language.	Focused, calm in mind and spirit, with easygoing optimism and a general sense of well-being. GABA stabilizes blood pressure, relieves pain, promotes the burning of fat, and helps build muscle.	Addictions, anxiety, panic attacks, heart palpitations, high blood pressure, cognitive impairment, headaches, diminished libido, seizures (including epilepsy), chronic pain, premenstrual issues. Deficiency personality: drama queen, unstable.	GABA is available as a nutritional supplement. Taken before bedtime, it helps with sleep. Tryptophan enhances the activity of GABA, as do the herbs valerian root and kava kava.
<i>Serotonin</i> Sometimes associated with the occipital lobes of the brain, but over 80% of serotonin is produced in the gut. It maintains mood, balance, regulates appetite and digestion, promotes sleep, and enhances memory. Its precursor, the amino acid tryptophan which is present only in protein foods, must be accompanied by some carbohydrate to reach the brain.	Peaceful demeanor, centeredness, enjoyment of life. Also the ability to fall and stay asleep, reasonable tolerance to pain, appetite and body temperature regulation, and normal libido. Serotonin helps us feel emotionally and physically nourished and satisfied.	Depression, irritability, obsessiveness, anxiety, low self-esteem. Also body pain, insomnia, eating disorders, hormone imbalances. Cravings for sugar, carbs, caffeine and other stimulants. Deficiency or excess personality: pointless rebellion, self-absorbed.	Tryptophan and its chemical relative, 5-hydroxy-L-tryptophan, are precursors of serotonin. Take it afternoon and evening, but only long enough to build up serotonin levels. Moderate exercise and exposure to light also help build serotonin levels.

what they should have been given all along: the knowledge of what exactly their children, and possibly they, were taking. Despite diligent efforts by the pharmaceutical cartel to hide, obscure, trivialize, omit, or outright falsify data about these drugs, concerned parents, doctors and journalists worked just as diligently to uncover the truth. What's astounding is not only that the drugs often exacerbate the very symptoms they're supposed to be alleviating—but Big Pharma knew the truth about these medications for years, and deliberately withheld the data.

One of the first articles on psychiatric drugs received substantial publicity after it was released in the late 1990s: "School Violence: The Psychiatric Drugs Connection." The author, Pulitzer Prize-nominated investigative reporter Jon Rappoport, wrote that the problems caused by Prozac® and other prescription mind-altering drugs was much more widespread than the *PDR*® and mainstream media were willing to disclose. He pointed out that a disproportionately large percentage of teenagers were on some form of antidepressant when their shocking, senseless murder rampages made national news.

Although drug-induced killings had occurred at least as early as 1986 (and probably before), the heavily publicized 1998 Oregon murders by Kinkel—and then the 1999 massacre at Columbine High School in Colorado by Harris and Klebold—catalyzed serious public investigation into the relationship between psychotropic drugs and subsequent murders. Heated public discussions were already being held about the need for more caring parental involvement in the children's lives, for school personnel to report aberrant student behavior, and for more thorough background checks with firearm sales. Also, the public was increasingly demanding that the entertainment industry refrain from pushing murder and violence as acceptable forms of fun. These points were important, and of course needed to be addressed. But the one critical factor that was conspicuously absent in reports from all but the most obscure (independent) media was drug treatment history. In these and other similar acts of violence, *virtually all of the teenagers were on legally prescribed drugs*—Prozac®, Zoloft®, Paxil® and/or Luvox®—used to treat depression and obsessive-compulsive disorder. It took several years for Eric Harris's autopsy report to become public. Apparently, the low "therapeutic" levels of the antidepressant Luvox® in his system at the time of death were not therapeutic at all. And Jeff Weise's antidepressant prescription had just been increased significantly. (See pages 53–55, and 62–63, for summaries of specific events.)

Rappoport quoted psychiatrist Joseph Tarantolo, president of the Washington chapter of the American Society of Psychoanalytic Physicians:

[The drugs] relieve the patient of feeling. He becomes less empathic, as in "I don't care as much," which means, "It's easier for me to harm you." If a doctor treats someone who needs a great deal of strength just to think straight and gives him one of these drugs, that could push him over the edge into violent behavior.¹²³

Psychiatrist Peter Breggin, author of *Toxic Psychiatry*, *Talking Back to Prozac*® and *Talking Back to Ritalin*®, told Rappoport:

With Luvox®, there is some evidence of a 4% rate for mania in adolescents. Mania, for certain individuals, could be a component in grandiose plans to destroy large numbers of other people. Mania can go over the hill to psychosis. . . . I have no doubt that Prozac® can cause or contribute to violence and suicide. I've seen many cases. In a recent clinical trial, 6% of the children became psychotic on Prozac®. And manic psychosis can lead to violence.¹²⁴

Breggin's longstanding reputation of being antagonistic to the pharmaceutical industry made it easy for his critics to dismiss him. But it was harder to ignore negative input from someone who worked for the manufacturer of the drug. In 1994 David Healy, consultant for Eli Lilly (the pharmaceutical conglomerate that produces Prozac®), conducted a study proving that antidepressants can induce suicidal tendencies. A 1995 issue of the *British Medical Journal* contained data linking Prozac® to increased suicide risk.¹²⁵ By 1996, the FDA had received 35,000 complaints about Prozac® alone. A review-study called "Antidepressants for Children" in a 1996 *Journal of Nervous and Mental Diseases* concluded that "despite unanimous literature of double-blind studies indicating that antidepressants are no more effective than placebos in treating depression in children and adolescents, such medications continue to be in wide use."¹²⁶

Rappoport cited numerous studies appearing in respected professional publications that are not routinely read by the general public. The February 1990 *American Journal of Psychiatry* chronicled six depressed people, not known to be suicidal, who developed "intense, violent, suicidal preoccupations after 2 to 7 weeks of fluoxetine [Prozac®] treatment." The obsessions with suicide lasted from 3 days to 3 months after the medication was withdrawn. According to the study, 3.5% of Prozac® users were at risk.¹²⁷ In "Emergence of self-destructive phenomena in children and adolescents during fluoxetine treatment," the authors reported "self-destructive phenomena in 14% percent (6 out of 42) of children and

adolescents (10 to 17 years old) who had treatment with fluoxetine (Prozac®) for obsessive-compulsive disorder.”¹²⁸ In yet another article, which appeared in the July 1991 *Journal of Child and Adolescent Psychiatry*, a 13-year-old boy was described as “full of energy,” “hyperactive,” and “clown-like”; but after taking Prozac®, he exhibited sudden and violent acts that were “totally unlike him.” And a 1991 issue of the *Journal of the American Academy of Child and Adolescent Psychiatry* reported that a depressed 10-year-old boy, after being treated with Prozac®, became “hyperactive, agitated, [and] . . . irritable,” making a “somewhat grandiose assessment of his own abilities.”¹²⁹ He also phoned a stranger and threatened to kill him. After the Prozac® was stopped, the symptoms disappeared.

Ritalin®—typically prescribed for attention deficit disorder (ADD), also known as attention deficit hyperactivity disorder (ADHD)—is also implicated in murderous rampages. Thanks to Rappoport’s research two decades ago, readers were also made aware of an extensive literature review published in the July 1986 *International Journal of the Addictions*. Titled “An Outline of Hazardous Side Effects of Ritalin® (Methylphenidate),”¹³⁰ it contained indexed journal articles pertaining to over 100 common symptoms. Toxic effects include aggressiveness, akathisia (the inability to remain seated, with the tendency to be in constant, often repetitive motion), brain damage, convulsions, paranoid delusions, insomnia, psychosis, terror, screaming, visual and auditory hallucinations, pathological thought processes, extreme withdrawal, and decreased REM sleep. REM is an acronym for “rapid eye movement.” These eye movements, made through closed lids, indicate dreaming. They occur an average of two hours a night as a normal part of the sleep cycle. A decrease in the amount of REM sleep can be highly detrimental to psychological and physiological health. When REM sleep is continually interrupted over long periods of time, signs of sleep disturbance occur, including the inability to mentally focus, lack of motor coordination, and emotional volatility. This sounds very like the psychotic and hallucinatory reactions described as “side” effects of Ritalin®.

Laypeople who don’t read “alternative” literature or do research on the Internet have limited access to data. What they believe is what the medical establishment wants them to believe—what their doctors tell them. Consumers are usually not permitted to see the handouts given to medical professionals. Most have never even seen a copy of the *PDR*®—an expensive, huge volume available only to

doctors, and often not found in libraries (unless an older volume is contributed when the donor obtains a new one). People tend to ignore the possibility that they themselves might (and probably will) experience toxic drug effects. As of this writing, laws in the US and New Zealand require pharmaceutical advertisements to be accompanied by long lists of the “side” effects of drugs. However, there’s discussion of eliminating this requirement. There are many factors that have made it hard for the public to believe the extent of a worldwide drug industry cover-up.

Physicians are not immune to the effects of selective information, either. Even though the *PDR*® is a source of valuable information, it’s not as thorough in its description of “side” effects of drugs as the in-depth articles published

in professional journals. Literature issued by the drug companies is likewise limited. For instance, as reported by two medical researchers, “Eli Lilly states in Prozac’s® information sheet that the drug can cause akathisia [restlessness, pacing, and anxiety]. However, the company has said that less than 1% of Prozac® users experience this side

effect, while a report in the *Journal of Clinical Psychiatry* has estimated that the actual share of Prozac® users who suffer from akathisia is 10% to 25%.”¹³¹ Unless doctors specifically take time to extensively search the medical literature for more comprehensive information, they are limited to drug company literature and *PDR*® summaries of edited data—unless, of course, they are being compensated in some way by the drug companies, in which case they’ll promote a drug even if it’s especially harmful.

The problem of lies and omissions is compounded by the existence of organizations that appear to serve the public but have ties to the drug industry. Consider, for example, the case of Ritalin®. Years ago, the nonprofit ADD support organization, CHADD (Children and Adults with ADD/HD), received almost one million dollars from the manufacturer of Ritalin®. Not coincidentally, at that time CHADD recommended Ritalin® for children with so-called attention deficit disorder. On its website today, it states that it derives approximately 27% of its total revenue from pharmaceutical grants. Similarly, when Marc Czarka was director of pharmaceutical affairs for Eli Lilly Benelux, he admitted that the company contributed money to the American Psychiatric Association.

Despite industry attempts to conceal the effects of psychotropic drugs, some media mentioned the emotional imbalances and violent Prozac®-induced behavior in the

teenagers involved in the Colorado shootings. Just two major newspaper headlines of February 7, 1991, were “Murder Trials Introduce Prozac® Defense” in the *Wall Street Journal*¹³², and “Suicidal Behavior Tied Again To Drug: Does Antidepressant Prompt Violence?” in *The New York Times*.¹³³ Coincidentally on that same day, in a letter to the editor in the *New England Journal of Medicine*,¹³⁴ three medical doctors expressed great concern about the effects of fluoxetine drugs. Citing accounts of their own patients as well as studies from other journals, they emphasized that fluoxetine causes suicidal thoughts and behaviors in people who were not previously suicidal.

Two decades ago, Rappoport wrote that mainstream media was “afraid to go after psychiatric drugs as a cause of violent crime,” partly because they know that “expert attack-dogs are waiting in the wings, funded by big-time pharmaceutical companies. There are doctors and researchers who have seen a dark truth about these drugs in the journals, but are afraid to stand up and speak out. After all, the medical culture punishes no one as severely as its own defectors.”¹³⁵

In October 2004, the FDA finally ordered pharmaceutical companies to include, on the labels of antidepressants, a warning that the drugs could cause suicidal thinking and behavior, along with other unusual behavioral changes in children and teenagers. Later, as even more Public Health Advisory notices were posted on the FDA website, the warnings increased in scope to include young adults, more harmful effects, and more drugs. Nevertheless, many more tragedies involving mind-altering drugs have occurred since Rappoport’s article was first published, and mainstream media is still married to Big Pharma.

In the past several years, many new studies have revealed other types of damage caused by antidepressants—notably, damage to children whose mothers take the drugs while pregnant. Assuming that the mothers don’t miscarry first, the children have a much greater chance of being born prematurely, of suffering from birth defects (including heart abnormalities), of becoming autistic, or of developing diabetes and becoming obese as youngsters. These newer studies have also found that certain antidepressants make people more susceptible to severe infections from *Clostridium difficile* and other pathogens. The drugs destroy many of the beneficial flora in the gut, thus making the immune response weaker.

Incredibly, the use of psychoactive drugs is increasing.

Lawsuits and the Right To Refuse Drugs

Parents of children who became delusional (and then killers) from taking psychotropic medications, know the heartbreak of seeing a formerly “good” child (albeit with problems) become an amoral monster. Fortunately, not all parents believe that doctors are omnipotent.

Colorado was one of the first states in the US to take a firm stand against the drugging of children. On November 11, 1999, the Colorado State Board of Education adopted a resolution to “encourage school personnel to use proven academic and/or classroom management solutions to resolve behavior, attention, and learning difficulties” because there exist sufficient “documented incidents of highly negative consequences in which psychiatric prescription drugs have been utilized for what are essentially problems of discipline.”¹³⁶

Fred A. Baughman, Jr., a medical doctor who was instrumental in getting the resolution passed, pointed out that the US has the highest number of drugged children in the world. He referred to an article claiming that ADHD was real, and that unless this “disease” was treated with addictive drugs (including Dexedrine®, Ritalin®, and Adderall®), adolescents and adults would later be susceptible to substance abuse. In rebuttal, he emphasized that there was no evidence to support the claim that ADHD is a genuine illness (more

on this shortly)—and furthermore, the drugs used for treatment were themselves addictive! For example, he pointed out, methylphenidate (an ingredient in Ritalin®) is “classified as a Schedule II, controlled substance [and is a] central nervous system (CNS) stimulant and shares many of the pharmacological effects of amphetamine, methamphetamine and cocaine.” A respected early study was cited, concluding that “children treated with these stimulants take up smoking earlier, smoke more heavily and are more likely to abuse cocaine and other stimulants as adults.” The problem was, ADHD was called a “disease,” and the children so diagnosed were considered “diseased” and “abnormal.” “Lacking a disease [and] lacking diseased children,” Baughman and the committee concluded, “there is no justification of giving such drugs. Nor is it legal to give such drugs to admittedly normal children.”¹³⁷

Colorado State Board of Education member Patti Johnson agreed. Testifying before the US House of Representatives on September 29, 2000, she reminded her audience that although educators are not legally

permitted to practice medicine, “financial incentives exist for schools to label children with learning disorders.” Parents, she continued, are coerced into giving their children medication.

[One parent was] told her son had ADHD. . . . The school’s special education director eventually admitted that she had coaxed the teacher to answer the questions of the checklist used to determine if the child had ADHD in a certain manner so her son “would get the help he needed.”

[Another parent] said he at first complied with the school’s direction to have his son take a stimulant drug. The drug caused his son to become violent; he began taking steak knives out of the kitchen and stabbing his stuffed animals. When the parent took him off the drug, the principal of the school began pressuring him to resume the stimulant—so much pressure that the matter is now in court and the father could forfeit parental rights if he disagrees with the decision of the court on whether or not to place his child on Ritalin®.

. . . The label of ADHD [in the American Psychiatric Association’s *Diagnostic and Statistical Manual of Mental Disorders*, or *DSM*] is assigned if the child exhibits such symptoms as not listening when spoken to, is forgetful, fails to finish homework, fidgets, talks excessively, etc.—*the typical behavior of a normal child*. [emphasis added] Parents of children said to have these disorders are generally told that it is a neurological disorder or a chemical imbalance in the brain. Yet . . . the National Institutes of Health on ADHD in November 1998 . . . reported that “we do not have an independent, valid test for ADHD, and there are no data to indicate that ADHD is due to a brain malfunction. . . .”¹³⁸

It took parents of children who were harmed to initiate lawsuits against “designer” poisons and the companies that make them. The first landmark lawsuit against Prozac® and its manufacturer, Eli Lilly, was initiated in the early 1990s. The plaintiff in this case, Fentress, made the accusation that Prozac® had induced murder. As “the first action involving Prozac®,” Rappoport observed, “it would establish a major precedent for a large number of other pending suits against the manufacturer.” Using data culled from (among other sources) an article by Michael Grinfeld called “Protecting Prozac®” that appeared in the December 1998 issue of *California Lawyer*, Rappoport described how the trial appeared to have been fixed. In an astoundingly weak argument against Lilly, Paul Smith, the attorney for the plaintiff, did not even refer to criminal

violations committed by Lilly on other occasions—information that would have greatly helped strengthen his client’s case. After deliberating only five hours, the jury returned with a verdict favorable toward Lilly. Smith could only have omitted the damaging evidence against Lilly to obtain a favorable verdict for the drug company. In return, the case would be settled out-of-court, *in secret*, between Lilly and the plaintiff. Judge John Potter, who presided over the case, asked lawyers for both sides if “‘money had changed hands.’” The lawyers said no—without, however, acknowledging that an agreement was [already] in place.”¹³⁹ Technically, the attorneys had not lied. No money had changed hands (yet).

That trial catalyzed an ongoing investigation against attorney Smith. Rappoport cited Grinfeld:

In court papers, [Judge] Potter wrote that he was surprised that the plaintiff’s attorneys [Smith] hadn’t introduced evidence that Lilly had been charged criminally for failing to report deaths from another of its drugs to the Food and Drug Administration. Smith had fought hard [during the Fentress trial] to convince Potter to admit that evidence, and then unaccountably withheld it.

In 1996, the Kentucky Supreme Court issued an opinion on all this: “. . . there was a serious lack of candor with the [Fentress] trial court and there may have been deception, bad faith conduct, abuse of the judicial process or perhaps even fraud.”¹⁴⁰

Sometimes complainants are paid to shut up. Subsequent cases against Lilly, until around the year 2000, Rappoport wrote, were settled without a trial, “with such strict confidentiality, that it is almost as if they never happened. This smoothness, this invisibility, keeps the press away.” Out-of-court settlements also discourage greater numbers of people from coming “with lawyers and Prozac® horror-stories of their own because they are not reading about \$2 million or \$10 million or \$50 million settlements paid out by Lilly.”¹⁴¹

Nevertheless, there were small victories. Although Eli Lilly persisted in denying the validity of the study published in the February 1990 *American Journal of Psychiatry* that linked suicides to the ingestion of Prozac®,¹⁴² one of its divisions, Dista Products, issued a brochure for doctors dated August 31, 1990, stating that in the future “suicidal ideation” would be included in the adverse events section of its Prozac® product information. Another victory (at least partial) occurred in 2000. It began when New York-based Michael Carroll was visited by the Department of Social Service, which threatened to take away his 4-year-old son Kyle if he *stopped* giving his son Ritalin®. According to an article in the *Christian*

Three million children in this country take drugs for problems in focusing. Toward the end of last year, many of their parents were deeply alarmed because there was a shortage of drugs like Ritalin® and Adderall® that they considered absolutely essential to their children's functioning. But are these drugs really helping children? . . .

In 30 years, there has been a twentyfold increase in the consumption of drugs for attention-deficit disorder. As a psychologist who has been studying the development of troubled children for more than 40 years, I believe we should be asking why we rely so heavily on these drugs.

Attention-deficit drugs increase concentration in the short term, which is why they work so well for college students cramming for exams. But when given to children over long periods of time, they neither improve school achievement nor reduce behavior problems. The drugs can also have serious side effects, including stunting growth. . . .

Stimulants generally have the same effects for all children and adults. They enhance the ability to concentrate, especially on tasks that are not inherently interesting or when one is fatigued or bored, but they don't improve broader learning abilities. . . . the effects of stimulants on children with attention problems fade after prolonged use. . . . Many parents who take their children off the drugs find that behavior worsens, which most likely confirms their belief that the drugs work. But the behavior worsens because the children's bodies have become adapted to the drug. Adults may have similar reactions if they suddenly cut back on coffee, or stop smoking.

To date, no study has found any long-term benefit of attention-deficit medication on academic performance, peer relationships or behavior problems, the very things we would most want to improve. Until recently, most studies of these drugs had not been properly randomized, and some of them had other methodological flaws. . . .

Putting children on drugs does nothing to change the conditions that derail their development in the first place. Yet those conditions are receiving scant attention. . . . the large-scale medication of children feeds into a societal view that all of life's problems can be solved with a pill and gives millions of children the impression that there is something inherently defective in them. . . .

The illusion that children's behavior problems can be cured with drugs prevents us as a society from seeking the more complex solutions that will be necessary. Drugs get everyone—politicians, scientists, teachers and parents—off the hook. Everyone except the children, that is.

Science Monitor, Michael had halted Kyle's medication because the drug not only failed to help the boy with his reading problem, but it made him withdrawn and unable to sleep or eat. "From the beginning . . . I kept asking for special-education classes," Michael said. "They just wanted him to sit still and to push him through the system." Fortunately, a judge ruled that the concerned father could stop drugging his child if he found another doctor who said that Ritalin® was unnecessary. After Kyle was taken off the drug, he regained his appetite, was once more "his old outgoing self," and "performed well in special-education classes at a different school."¹⁴³

More doctors and parents have been recognizing that children are being overmedicated—though for some young people, this recognition occurs too late. From a 2004 newspaper article: "At least 110 American kids have killed themselves while taking antidepressants during the past, new FDA data says. . . . Those reports . . . led a scientist for the Food and Drug Administration to conclude that most antidepressants raise the risk of suicide in children."¹⁴⁴

Consider this April 2004 story from *The New York Times*, in which one doctor stated bluntly, "There is no good reason to prescribe these pills."¹⁴⁵ Eventually, the Individuals with Disabilities in Education Act (IDEA) was amended to address the forced medication of children. Schools would no longer have the right to coerce parents into medicating their children as a condition of their child's attendance at school.

Nevertheless, even as this important amendment was becoming law in 2004, pharmaceutical manufacturers were replacing lost income from discredited drugs by creating new ones—and then denying responsibility for subsequent damage. This denial had fatal consequences. In February 2004, 19-year-old Traci Johnson hanged herself at Eli Lilly's Indianapolis clinic. Johnson, whom Lilly acknowledged had been healthy, was taking part in a clinical trial to see how high doses of the antidepressant Cymbalta® affected healthy volunteers. The young woman had been taking up to *six times* the recommended 60 mg daily dose for depressed subjects. She was being weaned from the drug when she committed suicide. The FDA ruled six months later that the antidepressant had played no role in her suicide—even though the agency had told ten drug manufacturers in March to strengthen suicide-related warnings on labels for antidepressant drugs.

Despite the obvious legal biases in favor of Big Pharma, lawsuits have escalated against both drug companies and individual doctors. These lawsuits have been instituted not only by individuals related to people who have been harmed, but also by groups of people in class action cases.

The following are just a few examples of both. (More lawsuits are cited at breggin.com, SSRISTories.org, and aboutlawsuits.com.)

- ◆ In January 2002, lawsuits in California and New York contended that the drug companies Novartis and Ciba-Geigy, along with the American Psychiatric Association and the organization Children and Adults with ADD, conspired to create an extremely broad-based definition of ADHD to ensure hefty sales and profits. (Unfortunately, the Court did not agree.)
- ◆ In February 2006, Brett Bennett of Fort Myers, Florida, sued Forest Laboratories for product liability and failing to warn consumers that Lexapro® could cause people to commit suicide. His wife was taking the (prescribed) antidepressant when she killed herself.
- ◆ In 2010, GlaxoSmithKline agreed to pay more than \$1 billion to settle hundreds of lawsuits brought by parents of children with birth defects caused by Paxil®.
- ◆ In 2013, Eli Lilly settled a wrongful death lawsuit filed by the parents of 16-year-old Peter Schilf of South Dakota. He had committed suicide four weeks after taking the antidepressant Cymbalta®. The same lawsuit stated that Lilly had failed to tell doctors about another suicide (in February 2004) of a 19-year-old student who killed himself while taking part in a company-sponsored trial of Cymbalta® for urinary incontinence.
- ◆ In 2013, GlaxoSmithKline settled a Paxil® class action lawsuit in California for \$8.5 million. The company had failed to tell doctors that the drug is addictive, and can cause severe withdrawal symptoms.
- ◆ In February 2014, a jury in Chicago, Illinois awarded \$1.5 million to a boy who developed akathisia and dyskinesia—severe movement disorders that cause spasms, twitches, and relentless agitation and motion—while taking Risperdal® and Zyprexa® for five years. He was also taking Zoloft® and Paxil®. The cases were brought against the two psychiatrists who had prescribed the drugs
- ◆ In May 2014, a \$700,000 out of court settlement was awarded to someone whose psychiatrist had unnecessarily prescribed the antipsychotics Risperdal®, Seroquel® and Zyprexa®. They caused irreversible tardive akathisia (abnormal, incessant movements due to a malfunction of voluntary muscles). One of the charges was the failure to obtain informed consent.

It's difficult to obtain more recent information because lawsuits are still being litigated.

Do ADD and ADHD Even Really Exist?

Some people who object to drugging children with potent, growth-inhibiting pharmaceuticals also question whether or not ADD (and its newer version, ADHD) are even true diseases. It cannot be denied that many children today have difficulty sitting still, learning, and being “obedient.” Putting aside the question if this last “difficulty” is truly a problem (except to those who want their orders followed without questions or arguments), we must ask: “Do these behaviors truly qualify as ‘diseases’?”

Let's look at some possible scenarios under which a child might be diagnosed. She's bored and restless and doesn't sit still in class. Instead of having her needs met with stimulating material that challenges her intellect, she's diagnosed with a disorder and forced to take medication. Another child is disruptive and unruly. He interrupts the teacher, teases his classmates, and can't pay attention to his lessons. Had the teacher or principal taken the time to talk with him, they would have learned that he sees his drunken dad hit mom every night. But instead, he's diagnosed with a disorder and forced to take medication. A third child is withdrawn, dazed, unfocused, unable to read. She suffers from emotional and sexual abuse; but instead, she too is diagnosed with a disorder and forced to take medication. In “The Hazards of Treating ‘Attention-Deficit/Hyperactivity Disorder’ with Methylphenidate (Ritalin),” Peter Breggin and Ginger Ross Breggin write:

Children don't have disorders; they live in a disordered world. . . . The list of criteria for ADHD . . . identifies children who are bored, anxious, or angry around some of the adults in their lives . . . These “symptoms” should not red flag the children as mentally ill [however]. They should red flag the adults as requiring new efforts to attend to the needs of the children. . . .

Children aren't bored, inattentive, undisciplined, resentful or violent by their individual natures; but the stigmatizing label ADHD implies that they are. These children are usually more energetic and more spirited, or more in need of an interesting environment, than their parents and teachers can handle. . . .

Children can benefit from guidance in learning to be responsible for their own conduct; but they do not gain from being blamed for the trauma and stress that they are exposed to in the environment around them. They need empowerment, not humiliating diagnoses and mind-disabling drugs. Most of all, they thrive when adults show concern and attention to their basic needs as children.¹⁴⁶

There's another, political aspect to ADHD diagnosing. Caroline Miller, editorial director of the Child Mind Institute, reports that from 2004 to 2014, the diagnosis of ADHD increased 40%. The Centers for Disease Control (CDC) has estimated that as many as 20% of teenage boys have ADHD! What could account for such an increase in a non-infectious "disease"? To answer this question, Miller summarizes data from the book, *The ADHD Explosion*. In certain states, which created laws that financially penalized schools whose students failed standardized tests, the rates of ADHD diagnoses rose.

How do ADHD diagnoses help schools [that are] at risk of losing their funding? First . . . for kids who do have ADHD, it should improve their performance in school, including their test scores. Second, it may help kids who are disruptive in class [to] settle down, which could improve scores for the whole class. . . . So, even if it doesn't help the child it might help the school.¹⁴⁷

Miller's point—that the huge increase in ADHD diagnoses was spurred by financial incentives to the schools—seems to contradict the claim that ADHD doesn't exist, because students scored higher on standardized tests after taking the drugs. This appears to suggest that their ADHD diagnoses were correct, and taking pharmaceuticals was the correct solution. However, as Dr. L. Alan Sroufe has stated (see Sidebar, page 70), drugs for ADD and ADHD do in fact increase concentration for the short term (which is why college students use them when cramming for exams), and stimulants do enhance the ability to concentrate (especially when performing a task that's inherently boring, like most schoolwork). Over the long term, though these drugs no longer exert the desired effect. They appear to help what's perceived as a brain "malfunction" because they propel a child to score better on exams that are specifically *unable to measure true intelligence and problem-solving skills*.

Essentially, amphetamines are useful for helping people of all ages focus on boring, repetitive tasks that don't require intellect, creativity, or insight. The nervous systems of children who are fed amphetamines aren't being allowed to grow completely or normally. The children's ability to develop skills, question authority, and view the world "outside the box" is being stunted.

One of the most interesting points Miller raised was that diagnoses of ADHD rose sharply for children living "near the poverty line."¹⁴⁸ This can indicate increased relationship stresses, which often occur in under-parented homes and in families who don't have enough money. It can also mean poor nutrition.

Carolyn Dean—a co-author of the earlier referenced "Death By Medicine," and with degrees as both a conventional physician and naturopathic doctor—has written about why a child might be excessively restless, fail to learn or follow instructions, and have abnormally high levels of anxiety. Some key points are:

- ◆ *Environmental Toxins*. This includes heavy metals, air pollutants, food preservatives, artificial sweeteners, and harmful electromagnetic emissions. (See pages 9–16 for a brief summary on electropollution.)
- ◆ *Antibiotics*. Even one course of antibiotic drugs can wipe out the beneficial flora in the large intestine that help us digest our food and even produce vitamins. Moreover, antibiotics can upset the digestive tract and irritate the brain (making them an overlooked cause of behavioral changes in children). They can also aggravate, and even cause, hyperactivity.
- ◆ *Candida albicans Infections*. A *Candida* overgrowth results from antibiotics. This noxious fungus also proliferates with a diet of junk "food." *Candida* toxins infiltrate the brain, causing innumerable physical symptoms from skin rash to weight gain, and psychological issues including, but not limited to brain fog, mania, depression, and even autism and schizophrenia. (Dr. William Crook's literature explores this in depth.)
- ◆ *Food Allergies*. Incompletely digested proteins from allergenic foods travel through the bloodstream and cross the blood-brain barrier, affecting potentially all centers of the brain. Glutinous grains, soy, corn, and pasteurized/homogenized milk are common allergens. Foods that are genetically engineered (discussed in detail in Chapter 3) also ruin the gut and cause many other problems.
- ◆ *Nutrient Starvation*. Without the proper raw materials, children cannot develop properly. One health writer writes, "ADD . . . has been coined to characterize children deficient in magnesium and iodine."¹⁴⁹

Dr. Richard Saul, a behavioral neurologist, has seen far too many children diagnosed with ADHD in his decades-old practice in Chicago, Illinois, US. He was well aware, he writes, of statistics from 2008 to 2012, which showed that the number of adults taking medications for ADHD increased by 53% while the number of young American adults taking medications nearly doubled.

While this is a staggering statistic . . . frankly, I'm not too surprised. . . . Every day my colleagues and I see more and more people coming in

claiming they have trouble paying attention at school or work and diagnosing themselves with ADHD. . . . It's an easy catchall phrase that saves time for doctors to boot. But can we really lump all these people together? What if there are other things causing people to feel distracted?

I don't deny that we, as a population, are more distracted today than we ever were before. And I don't deny that some of these patients who are distracted and impulsive need help. What I do deny is the generally accepted definition of ADHD, which is long overdue for an update. . . . I've come to believe based on decades of treating patients that ADHD—as currently defined by the *Diagnostic and Statistical Manual of Mental Disorders (DSM)* and as understood in the public imagination—does not exist. . . . Today, the fifth edition of the *DSM* only requires one to exhibit five of 18 possible symptoms to qualify for an ADHD diagnosis. . . . How many of us can claim that we have difficulty with organization or a tendency to lose things; that we are frequently forgetful or distracted or fail to pay close attention to details? Under these subjective criteria, the entire US population could potentially qualify. We've all had these moments, and in moderate amounts they're a normal part of the human condition. . . .

Over the course of my career, I have found more than 20 conditions that can lead to symptoms of ADHD, each of which requires its own approach to treatment. Among these are sleep disorders, undiagnosed vision and hearing problems, substance abuse (marijuana and alcohol in particular), iron deficiency, allergies (especially airborne and gluten intolerance) . . . and even learning disabilities like dyslexia, to name a few. Anyone with these issues will fit the ADHD criteria outlined by the DSM, but stimulants are not the way to treat them. . . . The drugs' addictive qualities are obvious. We only need to observe the many patients who are forced to periodically increase their dosage if they want to concentrate. This is because the body stops producing the appropriate levels of neurotransmitters that ADHD meds replace—a trademark of addictive substances. I worry that a generation of Americans won't be able to concentrate without this medication; Big Pharma is understandably not as concerned.¹⁵⁰

When Psychotropic Drugs Work

Mind-altering drugs do help a percentage of the population. Some parents of children on medication report improvement in many aspects of the child's behavior and emotional and mental states: the ability to be calmer, increased focus, better comprehension, augmented reading skills, better behavior, and so on. Some adults report benefits from taking mind-altering drugs, too. I witnessed this myself decades ago with one of my own psychotherapy clients. She described experiencing more stable moods, as well as partial relief from depression, while on one popular psychotropic medicine. I had no reason to doubt her account. How could I possibly argue that someone hasn't experienced what she says she has experienced?

My intention is not to condemn those who find relief from mind-altering drugs. But at what price is this "relief" obtained? If you're a parent, do you want your child to continue taking medications that interfere with the growth of his brain and body? Do you want her to suffer from effects that make her wish she was not alive to experience them?

It cannot be denied that medicated children are more docile, obedient, and less likely to think for themselves (except, of course, when they're "disobedient" in the extreme and kill people). However, are the risks of pumping kids full of psychoactive drugs worth the negative effects? Especially considering all the factors that can contribute to problems of inattention? These factors include nutrient starvation; toxins; an out-of-control Big Pharma eager to create diagnoses and peddle its wares; a financially stressed educational system hungry to receive additional funding and devoted to controlling children rather than helping them learn; and a moderately stressful or completely traumatic home life, which creates emotional problems. (Who can blame children in such environments for not paying attention in school?) I cannot see any reason to medicate children *until and unless all holistic options have been skillfully applied*. Even then, pharmaceuticals should be used with the utmost of care. However, this is rarely the case.

The Breggins write, regarding amphetamines: "At the doses usually prescribed by physicians, children and adults alike are 'spaced out,' rendered less in touch with their real feelings, and hence more willing to concentrate on boring, repetitive schoolroom tasks."¹⁵¹ Similarly, my psychotherapy client admitted that sometimes her own feelings didn't seem quite "real." We must ask if this medication-induced state is true serenity, or a stupor.

We have seen that there are ways to balance the brain that don't involve pharmaceuticals. Using natural methods requires guidance from a skilled and experienced practitioner, but it can be done. Properly administered natural methods don't harm others. And they don't injure the people who are using them. Isn't it worth a try?

The arguments that favor psychotropic drugs always seem to omit several considerations. One, what are the causes of the conditions diagnosed as depression, ADD, ADHD, manic-depression (bipolar disorder), and other forms of mental and emotional suffering? Two, what do we need to address the *root causes* of these presumed disorders, rather than simply mask symptoms with medications? Three, what are psychotropic drug users missing by not trying other modalities? And four, at what price are some people obtaining relief? Will a psychotropic drug user have a full life? Is the "relief" worth the "side" effects of physical and mental malfunction? Is the "relief" worth the chance of becoming so "altered" that s/he commits brutal crimes—or becomes a victim of one?

It's clear that severe depression, extreme lack of focus, and other undesirable psychological conditions correlate to chemical imbalances. But *correlation does not mean "cause."* Just as brain chemistry imbalances can produce emotional, mental and behavioral dysfunction, external conditions can affect brain chemistry. Some conditions not mentioned earlier include chemical contaminants (such as heavy metals and pesticides), malfunctions in absorption and utilization pathways, thyroid imbalances (which profoundly influence mood and affect a surprisingly high percentage of the population), and pathogens such as certain strains of *Streptococcus*. Even the overuse of television and video games alters the neurological pathways in the brain, as I'll discuss later in this chapter. Is there any surprise, then, that children are exhibiting aberrant behaviors and bizarre symptoms on such a grand scale? Unless the root causes of emotional upset and perceived misbehavior are addressed, relying on a foreign chemical to balance brain chemistry doesn't make sense. As holistic practitioners like to say, no one has ever had a Prozac® deficiency. It's imperative to address the diagnoses themselves.

I have devoted considerable space to the drugging of (mostly underage) children because, in a bizarre example of life reflecting art, we appear to be in the process of creating a nation of zombies. Gary Null et al. write:

Patients have the freedom . . . to refuse medical treatment even if it is recommended by their physician, and to be informed about their medical condition, the risks and benefits of treatment, and appropriate alternatives.

—Association of
American Physicians and Surgeons,
October 2000
aapsonline.org/testimony/vacresol.htm

A whole generation of antidepressant users has resulted from young people growing up on Ritalin®. Medicating youth and modifying their emotions must have some impact on how they learn to deal with their feelings. They learn to equate [the skill of] coping with drugs, and not their inner resources. . . . [Even the *Journal of the American Medical Association* admits] Ritalin® acts much like cocaine."¹⁵²

We must ask: Do we want to experience our feelings, which is what makes us human—or numb ourselves from our experiences, emotions and sensations? Do we want to be empowered to deal with life—or deaden ourselves while we're still living? If we choose numbness, are we prepared for the possibility of becoming a suicide or murder statistic?

Assuming a more optimistic scenario—that more detailed warnings are put on drug labels, and that these warnings are accessible to consumers—class action lawsuits by parents and doctors may be too little, too late. We must prepare for the possibility that new laws can be created absolving drugs companies of liability, even if it can be proven that the companies knew about the dangers before the drugs were marketed. It's up to parents to educate themselves if they want to protect their children. The subordinate legal status of children (not to mention their still-growing brains and nervous systems) makes them vulnerable to being poisoned in the name of "illness prevention."

Anyone—whether it's a government, legal agency, doctor, teacher, priest, or parent—who uses a position of authority to force you to ingest a medication with questionable benefits and severe "side" effects, is either woefully ignorant or doesn't care about your welfare. And any law that forces someone to take medication, that limits access to information, or prevents people from seeking recourse if they are harmed, does not care that people are becoming mindless, ignorant, powerless, and sick. As long as people remain blindly obedient to the allopathic paradigm of "It's broken, so let Big Pharma fix it," those at the highest ranks of power will exert even tighter control over the general population. If we allow these attempts at control to continue, we'll have no one but ourselves to blame. And our children will be the ones who suffer the most, disregarded as "collateral damage."

THE VACCINE CONTROVERSY

By definition, drugs are supposed to be administered to those who are ill. But there's an entire class of drugs intended to be given only to people who are well: vaccines (that is, at least until recently).

Until about the early 2000s, the medical community's official position was that vaccinations should be given only to people presumed healthy. This is because the sick are acknowledged to be too immunologically weak to handle the effects that the vaccines are designed to produce. However, the medical community appears to have reversed its original (wise) position; and now, most doctors routinely advocate vaccinating everyone, whether they are healthy or ill. During flu season, the media urges everyone—*especially* the elderly and the ill—to receive vaccinations. And now children, and even infants who have just been born, are routinely being given vaccinations, often five at a time.

Despite mainstream medicine's claims that vaccines are necessary to eradicate disease, there are many convincing rebuttals to this argument that vaccination proponents never address. I will discuss the history of vaccines, what's in them, how they work (usually, not as intended), the political climate surrounding their forced administration, how to lessen their negative effects, and alternatives to them altogether. I will also address rabies shots, which in the US are mandatory for pets and some livestock.

The Origin of Vaccines

In present-day United States and other technologically advanced countries, vaccines are so common that it may be difficult to believe the world ever got along without them. But, like any commodity, vaccines have a history—and, like any commodity, a marketing strategy as well. The official history of vaccines is a familiar one, because it's constantly repeated by mainstream medicine. However, as with so many things in life that appear to be true, the tale we're told by mainstream medicine may not be as simple (or accurate) as we've been led to believe. The truth is more easily understood with a curious, questioning, open mind.

The major push to use and promote vaccines is rightfully attributed to Edward Jenner, an 18th century Englishman. Although modern medicine calls Jenner a doctor, the truth is much more complex, as revealed when we examine literature that cites primary source materials from the 1700s and 1800s. One heavily annotated article by Jennifer Craig, "Smallpox Vaccine: Origins of Vaccine Madness," states that although Jenner set up a practice as a surgeon and fancied himself a country doctor, he had not

earned that title. She quotes Walter Hadwen, MD, who described Jenner in a speech presented in 1896:

Now this man Jenner had never passed a medical examination in his life. He belonged to the good old times when George III was King, when medical examinations were not compulsory. Jenner looked upon the whole thing as a superfluity. It was not until twenty years after he was in practice that he thought it advisable to get a few letters after his name. Consequently he communicated with a Scotch university and obtained the degree of Doctor of Medicine for the sum of 15 [pounds] and nothing more.¹⁵³

The account of Jenner's "discovery" is well known in medical circles. During that time, milkmaids sometimes contracted cowpox—similar to the much more virulent human disease, smallpox—from the cows they milked. Jenner heard that milkmaids who'd previously been infected with cowpox were subsequently immune to smallpox. So he designed an experiment, based on the theory that cowpox blisters festering in afflicted individuals would protect them later from smallpox. In May 1796, Jenner injected pus, which he'd scraped from the cowpox blisters of a milkmaid, into an 8-year-old boy. The boy developed a fever, but not a full-blown cowpox infection. Then Jenner injected the boy with live smallpox pathogens to see if the lad would develop smallpox. He did not. Then the boy was injected with smallpox a second time; and again, apparently nothing happened. Thus Jenner proclaimed his experiment a success.

The tales about the milkmaids that Jenner believed were either the truth (according to vaccine supporters) or rumors (according to vaccine opponents). After Jenner's death, a physician wrote that cowpox had been confused with smallpox because each disease contains the word "pox." "To a pathologist or epidemiologist, it is as truly nonsense to speak of cowpox becoming smallpox as it is legitimate nonsense to prove that a horse chestnut is a chestnut horse."¹⁵⁴ Even if the stories that Jenner had heard were true, he committed three serious infractions. One, he did not bother to confirm the tales of immune milkmaids, instead relying completely on heresay. Two, he performed an unethical experiment, the act of deliberately inflicting illness on another human being. Three, he drew conclusions that were not supported by sound science—if indeed, it could be called "science" at all. Based on *one test subject*, Jenner decided that his vaccine was successful as a medical treatment—which he tirelessly promoted as such. This is the origin of *all* present-day vaccines. Jenner is the man to whom the medical community sometimes refers as the "Father of Immunology."

Jenner's procedure, originally called "cowpoxing," was later referred to as *vaccination*, based on the Latin word for "cow," which is *vacca*. However, it was the Chinese who first used a rudimentary form of vaccination called *variolation*. It may have been practiced as early as 1000 BC, and was more widely used between the 14th and 17th centuries. Another heavily annotated article, "Vaccination: A Mythical History"—this one, by medical doctor Suzanne Humphries and Roman Bystrianyk—explains that the idea of vaccination:

was introduced to the Western world by Lady Mary Wortley Montagu in 1717 [or 1718, according to Jennifer Craig]. She had returned from the Ottoman Empire with knowledge of the practice of inoculation against smallpox, known as variolation. This type of inoculation was simply a matter of *infecting a person with smallpox at a time and in a setting of his choosing*. The idea behind inoculation was that, *in a controlled setting*, people would do better against the disease than if they contracted it at some possibly less desirable time and place in the future. [emphasis added] ¹⁵⁵

The early Asian practice of infecting someone in a controlled setting is similar to modern "chicken pox parties" or "mumps parties" (or any gathering featuring other communicable childhood diseases), where children are sent to play with an infected child so they will contract the disease and be treated in a conscientious manner. Significantly, the oldest forms of variolation involved exposure to smallpox scabs via the skin or inhalation, rather than by injection—which makes sense, because in daily living, the disease is contracted via touch or through the air. However, in her travels, Lady Montagu also encountered a more direct, crude predecessor to inoculations. "The old woman rips open the vein that you offer her," Montagu wrote, "and puts into the vein as much [smallpox] venom as can lie upon the head of her needle . . . [The people] are well for eight days. Then the fever seizes them and they keep their beds two days . . . then they are as well as before their inoculation." ¹⁵⁶

Throughout history, trends have often been started by famous people. With the practice of inoculation, it was no different. Soon after Lady Montagu's return to England, the upper classes were receiving vaccinations. Jennifer Craig reports that almost immediately, "two people died: a young servant in a Lord's household and the small son of the Earl of Sutherland. The church deplored the intervention in God's will, physicians deplored the influence of 'ignorant women,' and the public deplored the spread of the disease." Moreover, she writes, the

disease was spread because "inoculated people were fully contagious during their brief illness," and therefore "they could, and did, start epidemics." ¹⁵⁷ If vaccinated folk truly enjoyed a lower mortality rate than those who had naturally contracted smallpox, Humphries and Bystrianyk suggest that those improvements, rather than being due to inoculation, "had something to do with the fact that the wealthy had better access to more nutritious food and a cleaner environment than the majority of society." ¹⁵⁸

Meanwhile, Jenner was busy marketing his idea.

In 1798, Jenner published his results claiming lifelong protection against smallpox, using his discovery with only rumors to support his contention. While he promoted the use of his technique based on the tale that someone infected with cowpox would be immune to smallpox, there were doctors of the time who challenged this myth, *because they had seen smallpox follow cowpox*. At a meeting of the Medico-Convivial Society, Jenner was ridiculed over his practice. [emphasis added] ¹⁵⁹

Note that the Medico-Convivial Society medical gathering was not the first place in which prophylactic vaccination had been challenged. Much earlier, in 1764, an article called "The Practice of Inoculation Truly Stated" was published in *The Gentleman's Magazine and Historical Chronicle*. The author observed that because smallpox was a contagious disease, deliberately infecting more people would simply create new venues to spread it. Comparing the number of deaths from smallpox in the 38 years before the introduction of inoculation to the 38 years after its introduction, the author found that the number of deaths had *increased*, rather than decreased. "The practice of inoculation," he wrote, "manifestly tends to spread the contagion." ¹⁶⁰ Humphries and Bystrianyk agree that the "one major and generally unacknowledged drawback to variolation [was that] those inoculated could and did spread smallpox, creating more deaths than there would have been naturally." ¹⁶¹ However, this didn't stop Jenner from claiming that his experiment was the newest and best way to combat disease.

In 1799, three years after Jenner's one and only test case, a Mr. Drake repeated Jenner's experiment. He inoculated some children with cowpox material obtained from Jenner, followed by smallpox material—to test if the cowpox inoculation had been effective. All of the children developed smallpox. Humphries and Bystrianyk, referring to a published account from 1898, write that "Jenner received the report but decided to ignore the results because they were not in support of his theory." ¹⁶²

By the early 1800s, there were many documented cases of vaccine failure. “Dr. Lettsom, writing in 1806, tells us that whereas smallpox deaths for 42 years before inoculation were 72 per thousand, there were 89 per thousand in the 42 years after its introduction.”¹⁶³ In 1809, the *Medical Observer* recorded the names, dates, and locations of the people who had died from inoculations. One entry read, “The patient had been vaccinated, and the parents were assured of its security. The vaccinator’s name was concealed.”¹⁶⁴ A doctor wrote later, in “The Case Against Vaccination” (published in 1896): “The cow doctors could have told him [Jenner] of hundreds of cases where small-pox had followed cow-pox.”¹⁶⁵ And in 1817, an article in *The London Medical Repository Monthly Journal and Review*, Volume VIII, stated that “the number of all ranks suffering under Small Pox, who have previously undergone Vaccination by the most skillful practitioners, is at present alarmingly great.” [original spelling and punctuation intact]¹⁶⁶

In 1819, in an article called “On the Present State of Vaccination,” surgeon Thomas Brown wrote that after vaccinating 1,200 people, he was disappointed because people could still contract smallpox and even die from it. Therefore, he vowed, he would no longer support the practice.¹⁶⁷ This was a brave stance, considering that physicians were well compensated for administering vaccines (just as they are today). Craig explains how the medical profession rationalized the failure rates:

It didn’t take long before cases of smallpox among the vaccinated were reported. The first response was denial, but when the vaccinated were obviously afflicted, Jenner and his supporters said that the disease was milder in form. But when the vaccinated caught the disease and died, [vaccine supporters] had to come up with another explanation. Re-naming the disease did the trick—they didn’t die of smallpox, they died of the re-named disease: “spurious cowpox.”

Despite increasing evidence that vaccination with cowpox pus did not prevent smallpox, the practice continued. Physicians, for the first time, attended the healthy; 100% of their catchment areas could now be treated instead of the 10% who had contracted smallpox. As Dr. Hadwen so aptly remarked in 1896, “What Jenner discovered, though hardly original in its general principle, was that it pays far better to scare 100% of the fools in the world—the vast majority—into buying vaccine than it does to treat the small minority who really get smallpox and who cannot afford to pay anything. It was indeed a very great

Why G.B. Shaw Changed His Mind

George Bernard Shaw (1856–1950) was born in Dublin, Ireland. He was a social critic, journalist, novelist, co-founder of the London School of Economics, and advocate of equal rights for women. Although Shaw wrote prolifically about education, religion, class privilege, government and health, he’s probably best known for being a playwright. His stage play, *Pygmalion*, was adapted for a film, and later for a musical, called *My Fair Lady*. Shaw won a Nobel Prize in Literature in 1925, and an Academy Award in 1938 for his work on the film version of *Pygmalion*.

July, 1931

Dear George Bernard Shaw:

A few years ago I believe you stated that you were opposed to vaccination. It has been said that great men frequently change their minds, and I should like to ask whether you still condemn vaccination?

Will you forgive me if I ask whether you have ever been successfully vaccinated? The subject of vaccination is one that interests millions of persons, and is my excuse for asking these personal questions. With best wishes for a long, healthy life, I am,

Yours very truly,
Chas. F. Pabst, MD

London, July 19, 1931

Dr. Pabst:

I was vaccinated in infancy and had ‘good marks’ of it. In the great epidemic of 1881 (I was born in 1856) I caught smallpox.

During the last considerable epidemic at the turn of the century, I was a member of the Health Committee of London Borough Council, and I learned how the credit of vaccination is kept up statistically by diagnosing all the re-vaccinated cases as pustular eczema, varioloid, or what-not—except smallpox. I discovered a suppressed report of the Metropolitan Asylums Board on a set of re-vaccinations which had produced extraordinarily disastrous results. Meanwhile I had studied the literature and statistics of the subject. I even induced a celebrated bacteriologist to read Jenner. I have no doubt whatever that vaccination is an unscientific abomination and should be made a criminal practice.

VACCINE SCHEDULE, GREAT BRITAIN		
Vaccine	Age Administered	Details
5-in-1	Infants, 2 months. Infants, 3 months. Infants, 4 months.	Routinely offered to all babies. One jab is for diphtheria, tetanus, whooping cough (pertussis), polio and Haemophilus influenzae type b. This is the first dose. Second jab. Third jab.
Pneumococcal	Babies at 2 months, 4 months, and 12–13 months. Adults age 65 and over. Optional: students 18–25 years.	Babies receive 3 separate injections. Adults receive it once. People who are ill receive it either once or every 5 years. Those with long-term health problems, such as a serious heart or kidney disorder, should receive the vaccine too.
Rotavirus	Infants age 2–3 months.	Two jabs, at least one month apart. First dose must be given before 15 weeks; second dose must not be given later than 24 weeks. If baby is seriously ill with vomiting, diarrhea or fever, postpone injection until child is well.
Meningitis C	Infants age 3 months and 12 months, and children 13–15 years of age. Optional: students 18–25 years.	Infants receive two jabs spaced several months apart, and teenagers 13–15 years old receive “booster” shots. Acknowledged not to “protect” against another form of the disease, Meningitis B.
Measles, mumps and rubella (MMR)	Babies under 1 year old, and then between 3–5 years.	Two jabs.
Annual Flu— “Children’s” Flu	Any child over age 2.	Received annually, usually as a single dose of nasal spray squirted up each nostril.
4-in-1 pre-school booster, also known as DTaP/IPV	Children age 3 years, 4 months, to up until child begins school.	One jab is for diphtheria, tetanus, whooping cough (pertussis), and polio.
3-in-1 teenage booster, also known as Td/IPV	All young people 13–18.	One jab is for diphtheria, tetanus, and polio.

VACCINE SCHEDULE, GREAT BRITAIN		
Vaccine	Age Administered	Details
HPV (Human papilloma virus)	All girls age 12 and 13.	Two jabs 6–24 months apart. Girls who received first vaccine before September 2014 receive 3 jabs.
3-in-1 teenage booster, also known as Td/IPV	All young people 13–18.	One jab is for diphtheria, tetanus, and polio.
Annual Flu—Adults	Anyone.	One jab annually.
Shingles	Some adults over age 70.	One jab annually.
OPTIONAL: Tuberculosis (TB)	Babies from areas with high TB counts or whose parents or grandparents had TB; certain teens and adults considered “at risk”; travelers to certain areas.	One jab.
OPTIONAL: Hepatitis B	Drug users; sexually active; babies born to infected mothers; relatives of infected persons; people with liver or kidney disease; medical personnel of all kinds; prisoners.	Three jabs 4–6 months apart.
OPTIONAL: Chicken Pox (Varicella)	Children, pregnant women, people with weakened immunity, health workers.	Two jabs 4–8 weeks apart.
OPTIONAL: Cholera, Hepatitis A, Typhoid, Yellow Fever	Anyone traveling to a foreign country where there have been outbreaks of these diseases.	Special circumstances vary; adapted for traveling.

VACCINE SCHEDULE, UNITED STATES, mostly from birth through age 6 (simplified)		
Vaccine	Age Administered	Details
Hepatitis B	Birth, within 12 hours. Infants, 1–2 months. Infants, 6–15 months.	Routinely offered to all babies. Second dose. Third dose. A fourth dose is suggested under some circumstances.
Rotavirus 1-dose series 2-dose series 3-dose series	Infants, 2 months. Infants, 4 months.	
Pneumococcal (PCV13 vaccine)	Infants, 2 months. Infants, 4 months. Infants, 6 months. Babies, 12–15 months. Optional: students 18–25 years.	The Centers for Disease Control (CDC) lists a complex schedule of vaccine administration for children up to 18 years old who have chronic heart disease; chronic lung disease (including asthma); diabetes; cerebrospinal fluid leak; cochlear implant; sickle cell disease; HIV infection; chronic kidney failure; organ transplants; and cancerous conditions associated with radiation “treatment” and immunosuppressive drugs, including leukemia, lymphoma, and Hodgkin’s disease.
Tetanus, Diphtheria, and Acellular Pertussis (Tdap)	Infants, 2 months. Infants, 4 months. Infants, 6 months. Babies, 15–18 months. Children, 4–6 years. Adolescents 11–12 years old.	May also be administered to pregnant girls. This Tdap vaccine has a very complicated schedule depending on the manufacturer. There are also “booster” shots.
Inactivated Poliovirus Vaccine (IPV)	Infants, 2 months. Infants, 4 months. Infants, 6–18 months. Children, on or after 4 years of age.	The poliovirus is said to be inactivated. However, viruses lie dormant for long periods; and even pieces of virus that enter cells can cause damage.
Measles, mumps and rubella (MMR)	Babies, 12–15 months. Children, 4–6 years.	All schoolchildren are required to have 2 doses of MMR.

VACCINE SCHEDULE, UNITED STATES, mostly from birth through age 6 (simplified)		
Vaccine	Age Administered	Details
Chicken Pox (Varicella)	Babies, 12–15 months. Children, 4–6 years.	The second dose may be administered before age 4 if at least 3 months have elapsed since the first dose. The CDC has a schedule of catch-up vaccinations as well.
Flu: <i>Haemophilus influenzae</i>, type B	Infants, 6 weeks or 12 months, depending on vaccine manufacturer. Once a year thereafter.	The CDC has a very complicated schedule of when to administer additional doses, depending on various circumstances. A “Catch-up Schedule” is posted on its website.
Meningococcal conjugate vaccine	Minimum age: 6 weeks or 9 months, depending on manufacturer. Two doses: the “main” dose, with a “booster” shot. Those with increased risk of disease are advised to get more shots.	
Hepatitis A	First dose: babies, 12–23 months. Also advised for those said to be at increased risk for infection: travelers; homosexual males; users of oral and injectable recreational drugs; people with chronic liver or clotting factor disorders; laboratory personnel working with animals infected with Hep A.	Two doses, separated by 6 to 18 months.
HPV (Human papilloma virus)	Three doses for all girls age 11–13, though the girl can be as young as 9 years old. Sometimes boys are inoculated as well.	This is the only vaccine listed here given to young children after age 6. The Human papilloma virus is typically contracted through sexual activity.

discovery—worth thousands of millions. That is why this kind of blackmail is still kept going.” . . . When Jenner died in 1823, three kinds of smallpox vaccines were in use: 1) cowpox—promoted as “pure lymph from the calf,” 2) horsegrease—promoted as “the true and genuine life-preserving fluid,” and 3) horsegrease cowpox.

Following Jenner’s death, the vaccine establishment used one excuse after another to explain the failure of vaccination: the number of punctures was incorrect, or that re-vaccination was necessary, or that the lymph was impure. The smallpox deaths of vaccinated patients in [the] hospital were recorded as “pustular eczema.”¹⁶⁸

From 1820 to 1822, smallpox escalated to epidemic proportions in the north of England. In 1829, the British medical journal *Lancet* reported: “It attacked many who had had small-pox before, and often severely; almost to death; and of those who had been vaccinated, it left some alone, but fell upon great numbers.”¹⁶⁹ Seventy-three years after Jenner’s death, the medical community was still trying to undo the damage that he had created.

Nevertheless, enthusiasm for vaccines spread to other countries, including the US, France, and Germany. Clearly, though, vaccines weren’t delivering what they promised. “Data from Boston that begins in 1811,” analyze Humphries and Bystrianyk, “shows that, starting around 1837, there were periodic smallpox epidemics that culminated in the great 1872 epidemic.” The periodic episodes occurred in 1855, 1859, 1860, 1864, 1865 and 1867, just before that final infamous epidemic. From 1872 to 1873, there was:

the most severe smallpox epidemic since the introduction of vaccination. These repeat smallpox epidemics showed that the strict vaccination laws instituted by Massachusetts in 1855 had no effect at all. . . . In fact, more people died in the 20 years after the strict Massachusetts vaccination compulsory laws than in the 20 years before.

By this point, the medical profession no longer claimed lifelong protection against smallpox from a single vaccination. Instead, claims were made that vaccination made smallpox less likely to kill or that smallpox would be milder. Calls were then made for revaccination.¹⁷⁰

In 1869, back in the United States, *The New York Times* commented on the inoculation situation in England: “The public vaccinators have received immense sums from Parliament. . . . Other sums, also, which I cannot name, have been granted for the purpose of sustaining this monstrous fraud. Has ever a quack remedy produced so much gain?”¹⁷¹

It would seem to be impossible for a rational mind to conceive that a filthy virus derived from a smallpox corpse, the ulcerated udder of a cow, or the running sores of a sick horse’s heels, and cultivated in scabbed festers on a calf’s abdomen, could fail to have disastrous effects when inoculated into the human body.

—Maurice Beddow Bayly, MRCS, LRCP

June 1936

whale.to/vaccines/bayly.html

By the first part of the 20th century, the town of Leicester, in England, was widely reported in the news because the majority of its citizens refused vaccinations—despite grim prophecies that they were inviting a smallpox outbreak. To the surprise of many, deaths from smallpox proved far lower than when the vaccination rates had been high. Dr. J.W. Hodge’s article, “How Small-Pox was Banished from Leicester,” discussed how an unvaccinated

population was less susceptible to—and less afflicted by—the disease than vaccinated populations.¹⁷² In fact, figures analyzed by Humphries and Bystrianyk show that from 1859 to 1922, official deaths related to vaccination exceeded more than 1,600. “Official” figures were obtained only from the deaths that were acknowledged and reported; many more may have died from inoculations. Dr. Tebb wrote, in 1884: “Vaccination was made compulsory by an Act of Parliament in the year 1853; again in 1867; and still more stringent in 1871. Since 1853, we have had three epidemics of small-pox, each being more severe than the one preceding.”¹⁷³

Over time, symptoms of smallpox became much milder and the severity of the disease lessened. In fact, smallpox became much more difficult to diagnose, and was often confused with chicken pox. “By the 1920s,” report Humphries and Bystrianyk, “it was recognized that the new form of smallpox produced little in the way of symptoms, even though few had been vaccinated.” Despite how few people were vaccinated, however:

there was never a resurgence of smallpox. Even though smallpox was not a major issue, the practice of smallpox vaccination continued from the time of the last smallpox death in the United States in 1948 up until 1963. This resulted in an estimated 5,000 unnecessary vaccine-related hospitalizations from generalized rash, secondary infections, and encephalitis.¹⁷⁴

The Theory of How Vaccines Work—and the Reality of Why They Don't (and Can't)

The theory of how vaccines work is simple. One sentence on the College of Physicians of Philadelphia website states simply: “Vaccines work by mimicking disease agents and stimulating the immune system to build up defenses against them.”¹⁷⁵ This explanation sounds reasonable. But the reality is more complex—and problematic. Before I discuss how the reality deviates from the ideal, let us briefly review what happens in the body during an infection, how the body’s immune response normally mobilizes, and how a strong immune response offers protection.

The body’s natural immune response consists of many different types of immune cells. Just a few are B cells, NK (natural killer) cells, and T cells. All of them are a subset of *white blood cells*, but because they’re found in the lymphatic fluid they’re called *lymphocytes* as well. Another type of immune cell is called an *antigen-presenting cell* (APC). Each type of immune cell has a specialized function, and works with all the other types to recognize, tag, and destroy pathogens and microbial wastes so the body can then excrete them.

Certain types of immune cells, such as white blood cells, are equipped to recognize pathogens. The surfaces of all microorganisms that cause or contribute to disease contain *antigens*—biochemical markers, unique to each particular pathogen. In response to the antigens, some immune cells produce *antibodies*, which attach to the corresponding antigens like a key in a lock. Once a pathogen is recognized, the antibody either tags it for destruction, or prevents it from entering the body’s tissue cells. Antibodies are also produced in response to foreign proteins. The foreign proteins can appear in many forms: a mismatched blood transfusion, an incompletely digested food, an allergen, or even one’s own tissue proteins (in the case of an autoimmune disease).

The B cells and the T cells are responsible for creating copies of the original tissue cells that were exposed to the actual pathogens. This helps the body retain the “memory” of an encounter with a pathogen, so that in the future, if the same type of pathogen reinfects the host, the white blood cells will recognize, tag, attack, and eliminate the invader even more quickly and efficiently.

So how exactly do vaccines confer immunity in ways that the body’s own immune cells can’t? The Carrington College website states that “vaccinations ‘program’ the immune system to remember a specific disease-inducing microorganism by letting it ‘practice’ with a weakened, killed or inactivated version of the pathogen”¹⁷⁶ that’s dispensed in the inoculation. As you will see, there are

some serious flaws to this theory. Here are the five main types of vaccines, according to the website of the CDC (Centers for Disease Control) and other institutions, along with explanations of how they’re supposed to work:

- ◆ *Live, attenuated vaccine.* Used for viral infections including varicella (chicken pox), and the three in the MMR formula: measles, mumps and rubella. This contains a presumably “weakened” version of a viable virus to avoid causing serious disease in people who are vaccinated. The CDC cautions that the recipient of this type of vaccine must have a healthy immune system, admitting that “Even though these vaccines are very effective, not everyone can receive them.”¹⁷⁷ Live, attenuated vaccines are thought to be similar to a natural infection, so they’re regarded as “good teachers” for the immune response.
- ◆ *Inactivated vaccine.* Made with “inactive” or “killed” pathogens, such as the polio virus. The immune response to inactivated vaccines is presumably different than to “live” or “attenuated” (weakened) vaccines. Multiple doses are usually recommended as “necessary” to build up and maintain immunity.
- ◆ *Toxoid vaccine.* Used to prevent diseases caused by the toxins produced by bacteria. The toxins are “weakened” (and are now called *toxoids*); so presumably they cannot cause illness. It’s assumed that the immune response of someone receiving this type of vaccine learns how to contend with the natural toxin. One example of a toxoid vaccine is the DTaP, which contains diphtheria and tetanus toxoids.
- ◆ *Subunit vaccine.* Contains only parts (subunits) of a virus or bacterium, rather than the entire pathogen. The theory is that “side” effects to this vaccine are lessened because the vaccine contains only “essential” antigens rather than all the components of the pathogen. Pertussis (whooping cough) is manufactured into a subunit vaccine.
- ◆ *Conjugate vaccine.* Designed for bacteria whose antigens are coated with sugar-like substances called *polysaccharides*. Polysaccharide coatings on an antigen are believed to disguise it, thus making it difficult for the immature immune cells of some people (such as children) to recognize and respond to the antigen. Conjugate vaccines are supposed to *join together* (conjugate or connect) the polysaccharides to antigens, thus enabling the immune cells to recognize and handle the bacteria. *Haemophilus influenzae* type B (Hib) is made into a conjugate vaccine, and was specifically developed for children.

The Truth About the Centers for Disease Control and Prevention

The first word in the name is not “Center” but . . . “Centers.” There is no Center in Atlanta that does medical research or cures diseases. What is in Atlanta is merely a government administrative building which administers the many “Centers” throughout the United States. The Atlanta office is funded and operated by the [US] Federal Government. [However] The many different Centers are [independent corporations] mostly funded with private grant money from pharmaceutical companies who deal in drugs relating to the specialty of each of the many Centers.

If a Center in Montana, specializing in rare tropical reptilian viruses, accidentally discovers a new Framawitz Disease and finds that a drug called Gillibrulin will cure it, then the disease and the drug are owned by the pharmaceutical company which privately funded the medical research. . . . The purpose of the main office in Atlanta is to be a promotional agent and salesman for the pharmaceutical companies who “discover fictitious disorders” at the various “Centers” and then convince you that to prevent Framawitz Disease you need to be on a lifetime dose of Gillibrulin. . . .

In the last 20 years . . . I have identified 12 fictitious medical problems which have resulted in massive billion dollar profits to a few pharmaceutical houses. All of the medical problems were either man-made or don’t exist, and were hyped and promoted by the CDC. All of them [include] the words Disorder or Syndrome in their names. That’s because they are not legitimate diseases. . . . I call it bio-terrorism.

—Marshall Smith, “Fever and The Mystery Disease SARS: A Bio-terror Weapon Spreads Around the World”
BroJon Gazette, March 31, 2003

“It would be nice,” rhapsodizes the CDC, “if there were a way to give children immunity to a disease without their having to get sick first. . . . [Therefore] the antigens in vaccines are either killed, or weakened to the point that they don’t cause disease. However, they are strong enough to make the immune system produce antibodies that lead to immunity. In other words, a vaccine is a safer substitute for a child’s first exposure to a disease. The child gets protection without having to get sick. Through vaccination, children can develop immunity without suffering from the actual diseases that vaccines prevent.”¹⁷⁸

In theory, then, vaccines should work. But the reality is very different. Holistic chiropractor Tedd Koren states:

Researchers always assume that if there are high antibody levels after vaccination, then there

is immunity . . . But are antibody levels and immunity the same? No! Antibody levels are not the same as *immunity*. The recent mumps vaccine fiasco in Switzerland has re-emphasized this point. Three mumps vaccines—Rubini, Jeryl-Lynn and Urabe (the one withdrawn because it caused encephalitis)—all produced excellent antibody levels but those vaccinated with the Rubini strain had the same attack rate as those not vaccinated at all. . . .¹⁷⁹

The medical community has known about these statistics for a long time. Back in 1980, a team of scientists in the *New England Journal of Medicine* stated: “It is important to stress that immunity (or its absence) cannot be determined reliable on the basis of history of the disease, history of immunization, or even history of prior serologic determination.”¹⁸⁰ (*Serologic determination* is the diagnostic identification of antibodies in a bodily fluid—in this case, in the serum or blood plasma.)

The very rationale for administering vaccines is riddled with misconceptions. The CDC’s claim—that children don’t suffer from the diseases that vaccines are supposed to prevent—is false. Children (and adults) do get sick from inoculations, often seriously. Sometimes they die.

I’ll discuss illness and death from vaccines in more detail shortly; but for now, I cannot overemphasize this critical point. *Antibodies cannot be equated with immunity*. When pharmaceutical companies claim that a vaccine is “effective,” they simply mean that the vaccine has succeeded in forcing the body to create antibodies against the pathogen(s) that are in the vaccine. Now, most doctors consider a high antibody count desirable because they have been trained to believe that a high antibody count indicates a strong, active immune response. But people with antibodies to a disease can, and do, contract the disease. After being vaccinated, they may develop the very disease against which they’ve been inoculated. The presence of antibodies indicates *only* that a person (or animal) has recently been challenged by a particular pathogen. Antibodies = *challenge*, and nothing else.

On the other hand, there are those with no detectable antibodies in their system, yet who enjoy strong immunity. The *lack* of an antibody response (called a *titer*) does not mean that an individual lacks immunity to the disease. And it doesn’t mean that an individual hasn’t been challenged by a pathogen. The lack of an antibody response simply means that the individual has not *recently* mobilized any immune cells. The immune cells in a normally functioning human or animal should respond *only* when challenged by a disease. If there hasn’t been a recent exposure, a healthy person or animal should not be producing antibodies. If

someone is producing antibodies when there hasn't been a recent exposure, this means that the immune function is *hyperactive*—overreacting. To analogize, you see a sleeping kitten but have a panic attack as though a bear were charging at you. In such a case, an autoimmune condition—an overreaction of the immune cells—is likely to exist. Not surprisingly, many autoimmune conditions are either exacerbated or outright caused by vaccines. The immune cells correctly perceive that the foreign proteins (contained in all vaccine formulas) don't belong in the body, and therefore launch an antibody storm to attack them.

The presence of antibodies, then, cannot be interpreted simplistically. In fact, establishment medicine has long recognized that the presence of antibodies is only part of a healthy immune response. Researchers know that memory cells play an even more important role, because it's memory cells that prompt the other immune cells to create antibodies and send them to the appropriate sites. Also, memory cells don't need reminders to keep producing antibodies, as summarized by the title of an article in a 1999 edition of *Science Magazine*: “Memory T Cells Don't Need Practice.”¹⁸¹

Scientists never found a way to test and monitor memory cells. But they have been able to develop tests that can assess an antibody response. Could this be why, with vaccine promotion, the spotlight is on antibodies?

An infant . . . receiving up to 13 vaccines . . . [at the same time, is taking] 13 medications at once. . . . Not one vaccine has ever been tested according to the scientific gold standard, that of a double-blind, placebo-controlled study. . . . Many vaccines contain ingredients that have never been clinically approved by the FDA. . . . Vaccine making pharmaceutical companies are permitted by the FDA to do their own safety testing, with no oversight and no verification from a financially independent entity. . . . They do not use placebos for controls.

“Vaccines: Elimination Mandatory!”
September 5, 2016
ageofautism.com/2016/09/vaccines-elimination-mandatory.html#more

What's In Vaccines and Their Effects

Vaccines are drugs that are more than merely ineffective. They actively reduce immune function because they contain dangerous foreign materials that were never meant to be in our bodies, and thus cannot be metabolized or excreted easily (if at all). The “main” ingredients are the pathogens against which we are supposedly being immunized. But there are many other ingredients too. Some are used as preservatives. Some are irritants, intended to stimulate immune cell activity. Still other ingredients are supposed to ensure that the pathogens remain inactive (a goal that's almost never accomplished).

Any one of the following substances in vaccines can cause a severe negative reaction. Usually, people aren't told what's in the vaccines, even if some of the ingredients are common allergens. (Not all of these ingredients are found in every vaccine, but many of them are.)

Altered Pathogens

All inoculation formulas contain viruses or bacteria, whole or in partial pieces, in different states of presumed activity. In their unaltered state when infecting the body in a “normal” way, viruses can wreak havoc. They penetrate the cell membrane of the host, appropriating the host's DNA and RNA in order to thrive and reproduce. Viruses are known for their ability to remain dormant for long periods of time, often hiding in the bodily tissues—until they're reactivated by stressors, including illness. The website of The Tech Museum of Innovation (supported by the Department of Genetics at the Stanford School of Medicine in San Jose, California) states:

DNA is constantly subject to mutations, accidental changes in its code. Mutations can lead to missing or malformed proteins, and that can lead to disease. . . . Some mutations happen during cell division, when DNA gets duplicated. Still other[s] . . . are caused when DNA gets damaged by environmental factors, including UV radiation, chemicals, and viruses.¹⁸²

What might happen, then, when *altered* viruses are administered in vaccines? The two basic methods of preparing viruses for vaccines are explained by homeopathic veterinarian Dolores Sánchez -Peñalver.

Though some vaccines are referred to as “killed” they are not truly killed. They are instead “inactivated” . . . generally with heat, radiation, or chemicals. . . . “Modified live” [also called “weakened virus”] vaccines are made up of *particles* of live viruses that have been altered in a laboratory by passing the virus through animal tissue repeatedly to partially break it up and reduce its potency. . . . The reason for using only parts of the viruses in these vaccines is so that the “attenuated” viruses will be “non-disease causing.” *In theory* the virus cannot reproduce, multiply, and create pathology. . . . [But in reality,] viral agents are fully capable of reproduction [and causing illness] within the cells of the animal into which they have been injected. [emphasis added]¹⁸³

Resolution Concerning Mandatory Vaccines

Based in Tucson, Arizona, United States, the Association of American Physicians and Surgeons was established in 1943 as a voice for “private” physicians.

There are increasing numbers of mandatory childhood vaccines, to which children are often subjected without meaningful informed consent, including information about potential adverse side effects. . . . The process of approving and “recommending” vaccines is tainted with conflicts of interest. . . . Safety testing of many vaccines is limited and the data are unavailable for independent scrutiny, so that mass vaccination is equivalent to human experimentation. . . . AAPS calls for a moratorium on vaccine mandates and for physicians to insist upon truly informed consent for the use of vaccines.

Patients have the freedom . . . to refuse medical treatment even if it is recommended by their physician, and to be informed about their medical condition, the risks and benefits of treatment, and appropriate alternatives.

The AAPS calls for a moratorium on vaccine mandates and for physicians to insist upon truly informed consent for the use of vaccines.

So, even if a virus cannot reproduce in its usual or customary manner, this doesn’t mean that it’s safe. *By their very nature, viruses, regardless of their form, have the potential to become infectious at any time.* Anyone who’s been infected by *Herpes* once, and then has another outbreak when under stress, knows this. Establishment medicine knows this too. It even has a term for this “viral potential”: *latency* or *dormancy*. Viruses, *including their proteins*, can remain dormant in a body until conditions change that allow them to become active. The abstract for the article, “Virus reactivation: a panoramic view in human infections,” which appeared in the April 2011 issue of *Future Virology*, explains how this occurs:

Another mode of virus infection is the latent phase, where the virus is “quiescent” (a state in which the virus is not replicating). A combination of these stages, where virus replication involves stages of both silent and productive infection without rapidly killing or even producing excessive damage to the host cells, falls under the umbrella of a persistent infection. Reactivation is the process by which a latent virus switches to a lytic phase of replication. [In the *lysogenic* phase, a virus attaches to the DNA of the host, and, without destroying

the host cell, replicates when that cell divides. In the *lytic* phase, a virus overtakes the host cell and reproduces; and after the cell is completely filled, it bursts, releasing more viruses to infect additional cells. The lytic cycle is the more common way for viruses to spread.] Reactivation may be provoked by a combination of external and/or internal cellular stimuli [in other words, stressors]. . . . *This article examines the published literature and current knowledge regarding the viral and cellular proteins that may play a role in viral reactivation.* The focus of the article is on those viruses known to cause latent infections, which include herpes simplex virus, varicella zoster virus, Epstein-Barr virus, human cytomegalovirus, human herpesvirus 6, human herpesvirus 7, Kaposi’s sarcoma-associated herpesvirus, JC virus, BK virus, parvovirus and adenovirus. [emphasis added]¹⁸⁴

The medical community is so aware of the viability and activity of viruses (or pieces of them) after inoculation—for a few weeks, years, or even decades—that they even have a name for it: *shedding*. *When a virus sheds, it’s active and transfers to others.* This is how an illness can be caught from *vaccinated* individuals.

Here is a simple summary. Viruses are resilient. They take over the host’s DNA. Although they appear to be inert, they can be activated at any time, prompted by an almost unlimited number and variety of stressors. One of those stressors is another virus—or, as stated in the previously quoted *Future Virology* article abstract, *pieces of viruses*, the “viral and cellular proteins.” *All* viral genetic material damages our own genetic code and deteriorates our immune response in a multifaceted manner.

The problem is, foreign material in the form of unnaturally weakened or “killed” viruses is present at too low a level to stimulate the body’s normal defenses. But it does not readily leave our tissues, and the body responds to its presence in an abnormal way. Nutritional biochemist A. Van Beveren, PhD, writes:

The body does not usually tolerate viruses unless they have been weakened (so as not to awaken a strong response) or tricked through a route (usually injection) that bypasses . . . organs and functions that would inevitably lead to normal, natural expulsion. But [by being] synthetically weakened and directly introduced into the bloodstream, these bits of aberrant nucleoproteins are capable of remaining latent toxicants for many years without continually provoking acute illness, yet keeping the defense system restless and “on guard” almost indefinitely.¹⁸⁵

Being continually “on guard” causes intense stress. The psychological signal is anxiety and the physical indicator is disease. Because “killed” viruses migrate directly into the DNA, the body—responding differently than it would to “normal” viruses—is not signaled properly to stop these “killed” viruses. But eventually, Van Beveren explains, the weakened viruses become too plentiful for the body to ignore. Enough weakened viruses are incorporated “into an appropriate chromosome [of the body’s cells,] and start the production of non-self proteins, [that] the only proper response from the organism must be to make antibodies—against its own cells.”¹⁸⁶ This explains the recent astronomical increase of chronic and degenerative autoimmune diseases. The body attacks itself, no longer able to recognize its own cells due to the gradual, stealthy, unnatural introduction of foreign material.

As long ago as 1976, at a seminar sponsored by the American Cancer Society, Rutgers University professor Robert Simpson warned of a similar autoimmune reaction in response to vaccination. “Immunization programs against flu, measles, mumps, polio, and so forth, may actually be seeding humans with RNA to form latent proviruses in cells throughout the body. . . . When activated under the proper conditions . . . [these proviruses] could cause a variety of disease.” Some of the conditions he named were rheumatoid arthritis, Multiple Sclerosis, systemic lupus erythematosus, Parkinson’s, and “possibly cancer.”¹⁸⁷ Additional conditions, says Van Beveren, with some level of autoimmune dysfunction, include hemolytic anemia, granulocytopenias, immune thyroiditis, sympathetic ophthalmopathy, chronic active hepatitis, polyarthritis, rheumatic fever, endomyocarditis, periarteritis nodosa, Addison’s disease, atrophic gastritis, pernicious anemia, immune pancreatitis, primary biliary cirrhosis, thrombocytopenias, and ulcerative colitis. Generalized glandular and organ damage, allergies, developmental disorders, and diseases like encephalitis—which cause erosion of the myelin sheath that covers the nerves—can also be vaccine-related (and often are).

“The thymus gland in vaccinated children,” Van Beveren explains, “atrophy much more, much faster, than in countries whose children are allowed to initiate a generalized inflammatory response.”¹⁸⁸ Moreover, there are implications for children whose parents have been vaccinated. The title of an article in *Discover*—“Dormant viruses can hide in our DNA and be passed from parent to child”—says it all.¹⁸⁹

Although vaccinations are now routinely given to babies, and adults who are weak, ill and elderly, safety studies for vaccines are done solely on small populations of healthy volunteers. Usually, no testing is done at all.

Waste Products from Humans and Animals

Other vaccine ingredients (which could also be considered “primary”) are as foreign to the body as viruses. This is not a complete list, but it’s representative of the foreign animal and human tissue that vaccines contain.

- ◆ *Dried Pus.* A protein-rich fluid of dead leukocytes (white blood cells) that accumulate at a diseased site to combat infections. Pus was one of the original ingredients in the first inoculations.
- ◆ *Scabs.* A hard coating on the skin made of blood platelets (similar to a blood clot), which forms when a wound heals. This was one of the original ingredients in the first inoculations.
- ◆ *Calf Serum.* Blood plasma from aborted calf fetuses, with the red blood cells removed. This fluid is used to provide a nutrient broth for culturing various viruses.
- ◆ *Chick Embryo.* This is used to grow the pathogens for rabies, yellow fever, and influenza vaccines.
- ◆ *Army Worm Cells.* Cells, usually from the ovaries of *Spodoptera frugiperda* (sometimes called “insect cell line” or “expresSF+”), used to speed the process of producing vaccines, typically used for influenza.
- ◆ *Monkey and Dog Kidney Cells.* Utilized to support the growth of certain viruses used in some vaccines, including formulas for polio, encephalitis, rotavirus, and influenza.
- ◆ *Pig, Sheep, and Horse Blood.* Sometimes accompany the animal cells that are part of the vaccine formulas.
- ◆ *Mouse and Rabbit Brain.* Used as a growth medium for the virus in the rabies vaccine.
- ◆ *DNA from Aborted Human Fetuses (Human Fetal Diploid Cells).* Used to grow viruses for various vaccines, including adenovirus, rabies, Hepatitis A, Hepatitis B, MMR, and varicella (chicken pox).

The medical community makes a point of stating that these materials are sterilized, but this is a ludicrous claim. By definition, such byproducts from blood and tissues are dirty. By definition, pus and cellular protein particles are waste. Hospitals try to reduce infection by sterilizing equipment and keeping operating rooms free of contaminants such as blood, pus, and tissue—the very substances that are injected into the body as inoculations. If this material is harmful enough to avoid touching, why is it safe to inject?

A medical writer points out that one huge problem with these various decomposed, foreign proteins—

“biological substances composed of animal cells”—is that “they enter directly into the bloodstream,” which allows them to “become part of our [own] genetic material.”¹⁹⁰ These proteins, which are the genetic material of cells from other species, can also be implanted into human tissue by any viruses that are in the vaccines. Remember, viruses enter any cells easily and appropriate the host’s DNA. This is why they’re often used by researchers to deliberately escort other (foreign) materials into the cells.

Many vaccine ingredients are obtained in a horribly cruel manner. Sentient, healthy dogs and monkeys are deliberately infected. Then workers collect the products of disease from these suffering animals.

Dirty byproducts are invited into the body every winter that people line up for flu shots, every time parents accept vaccines as a condition for their children being able to attend school, every time a doctor—in the name of “healing”—jabs an infant. On so many levels, there is no justification for putting medical waste into the body.

Heavy Metals

Mercury. Vaccines contain *thimerosal*, a compound that’s about 50% mercury by weight. Used in vaccines as a preservative due to its antifungal properties, thimerosal, says the FDA, has a “long record” in “preventing bacterial and fungal contamination of vaccines.”¹⁹¹ Fungi tend to grow in vaccines containing many different types of bacteria, compared to single-pathogen vaccines that do not promote fungus growth as readily. Because multiple-purpose vaccines are cheaper to produce than single-purpose vaccines, thimerosal is widely used.

Toxicologists rightly regard mercury—widely known as a *neurotoxin* (nerve poison)—as one of the most lethal substances on Earth. The website of the United States Environmental Protection Agency bluntly states: “All forms of mercury are quite toxic, and each form exhibits different health effects.”¹⁹² Gary Null, PhD and Martin Feldman, MD, summarize research studies gleaned from respected medical journals:

Promotion of the Gardasil® Vaccine: A War on Girls—and Now Boys, Too

The Gardasil® vaccine, distributed by Merck & Co., is supposed to produce immunity to the human papilloma virus (HPV), which is implicated in genital warts and cervical cancer. (Cervarix® from GlaxoSmithKline is another brand name for a similar formula.) First marketed to girls as young as age 9, to be taken in three doses over a six month period, the vaccine is now marketed to boys age 12 and over, for mouth and throat cancers supposedly acquired during oral sex. The FDA approved the vaccine in 2006, and the CDC encourages all boys and girls to take it.

No data exists showing that these vaccines prevent cervical cancer. The two testing periods—5 and 8.4 years—were too brief because cervical cancer can take 40 years to manifest from the onset of an HPV infection. Just several of the vaccine’s adverse effects include autoimmune conditions; early menopause; chronic fatigue; brain damage, convulsions, seizures and paralysis; deafness; blindness; lethal inflammatory cardiovascular disorders; cervical cancer itself; and death.

Fifteen-year-old honor student Gabi Swank was one inoculation casualty. She said she felt pressured into being vaccinated by incessant TV advertisements. Not warned of any undesirable effects, she suffered two strokes, resulting in partial paralysis and vision loss, and now often must use a wheelchair. Thirteen-year-old Jenny Tetlock, 15 months after being inoculated, developed a degenerative muscle condition that left her almost totally paralyzed. And a daughter of Dr. Scott Ratner, after her first Gardasil® dose, was affected as well. She became, he stated, a “chronically ill, steroid-dependent patient with autoimmune myofasciitis. I’ve had to ask myself why I let my eldest of three daughters get an unproven vaccine against a few strains of a nonlethal virus that can be dealt with in more effective ways.”¹⁹³ In 2007, 1,700 girls in the US alone reported adverse effects. In 2012, 4,700 adverse effects were reported in the UK. However, of 200 claims filed against the manufacturer in the US, only 49 have been compensated for injury caused by the vaccine. (The 49 claimants received about \$120,000 each.) Even nursing infants have died whose mothers received the vaccine: one of the earliest reports was filed in the Vaccine Adverse Event Reporting System on September 1, 2010.

A 2013 *Annals of Medicine* article reported: “The world’s leading medical authorities state that HPV vaccines are an important cervical cancer prevention tool, [but] clinical trials show no evidence that HPV vaccination can protect against cervical cancer. . . . In the Western world cervical cancer is a rare disease with mortality rates that are several times lower than the rate of reported serious adverse reactions (including deaths) from HPV vaccination.”¹⁹⁴ Even Dr. Diane Harper, a former Merck employee who helped get Gardasil® approved, criticized the vaccine. She says that no data beyond five years has shown the vaccine’s effectiveness, and consumers should be warned of its dangers.

After four girls died in India in 2010, the drug was banned. In Germany, scientists stated that the HPV strains most implicated in cervical cancer were not even in the vaccine, so they couldn’t support it. In 2015, the Japanese government recommended that no one take Gardasil® due to all the negative reactions. In the US, this vaccine is still heavily marketed because of politics, not health. Just one example of many: Texas governor Rick Perry issued an executive order in 2007 that all Texas girls be vaccinated with Gardasil®—after his former chief of staff became a lobbyist for Merck. Merck had given thousands of dollars in political donations to the governor.

Mercury exposure has been associated with nerve cell degeneration, adverse behavioral effects, and impaired brain development. It also has been linked to degenerative chronic conditions such as Alzheimer's disease. The developing fetal nervous system is the most sensitive to its toxic effects, and prenatal exposure to high doses of mercury has been shown to cause mental retardation and cerebral palsy.¹⁹⁵

To give you an idea of how thimerosal is used, the multi-dose flu vaccine contains 51,000 ppb (parts per billion) of mercury. This amount—51,000 ppb—is 25,000 times more than the legal maximum limit for mercury in drinking water, as established by the United States Environmental Protection Agency (EPA). Moreover, mercury that's injected is completely absorbed, one hundred percent. This makes it even more toxic than when it's in a glass of water that you drink, or in the large fatty ocean fish that you eat for your meal.

Despite mercury's deserved reputation as a poison, the mercury compound thimerosal is promoted by the medical establishment, the FDA, and even the EPA as the "helpful" and "safe" form of mercury, compared to other types. There is so much confusion and misinformation surrounding thimerosal that we need to take at least a brief look at the three different forms of mercury and their widely acknowledged effects.

- ◆ *Elemental / Metallic / Inorganic Mercury (Chemical Symbol is Hg).* Alone, unbound to any other substance, mercury is a thick silvery liquid at room temperature. (Some readers may remember, as children, playing with mercury globules, which are also known as "quicksilver.") Even short-term exposure causes damage to the central nervous system (CNS) in the form of tremors, mood changes, and delayed sensory and motor nerve function. Chronic (long-term) exposure causes additional problems of a psychological nature, such as irritability and excessive shyness.
- ◆ *Inorganic Mercury Compounds.* In the field of chemistry, *inorganic* means "without carbon." Inorganic mercury compounds are formed when mercury combines with any other element—for example, chlorine, sulfur or oxygen—*except* carbon. One common mercury compound is a salt called mercuric chloride. Oral ingestion causes nausea, vomiting, and severe abdominal pain. Chronic exposure causes kidney damage, abnormal development, and tumors, in (among other areas) the stomach, thyroid, and kidneys.

- ◆ *Organic Mercury Compounds.* In the field of chemistry, *organic* means "with carbon." Organic mercury compounds are formed when mercury combines with not only carbon, but some other elements too. Methylmercury is one of the two most common organic mercury compounds. Acute exposure causes developmental abnormalities and CNS damage, including blindness, deafness, and impaired perception. Chronic exposure causes additional CNS damage, including blurred vision, speech difficulties, visual field constriction, lethargy, and paresthesia (a sensation of tingling, pricking, or burning on the skin). Children of women who ingested high levels of mercury compounds while pregnant have a much greater risk of developing cerebral palsy, problems with motor coordination and balance, blindness, and mental retardation.

Whether in its single-element form or combined with another element as a compound, mercury is deadly. But what about thimerosal? As mentioned, highly toxic methylmercury is one of the two most common organic mercury compounds. The other common organic mercury compound is *ethylmercury*. When thimerosal is metabolized by the body, it breaks down into ethylmercury.

Both methylmercury and ethylmercury (thimerosal's byproduct) travel to all body tissues, and can even cross the placental and blood-brain barriers. But the medical establishment claims that ethylmercury is safe because (unlike methylmercury) it's excreted quickly by the body. In fact, the FDA website states, thimerosal "is metabolized or degraded to [presumably harmless] ethylmercury and thiosalicylate. Ethylmercury is an organomercurial that should be distinguished from methylmercury, a related substance that has been the focus of considerable study."¹⁹⁶

However, even the FDA acknowledges that "some infants could have been exposed to cumulative levels of mercury during the first six months of life that exceeded EPA recommended guidelines for safe intake of methylmercury." But, it assures us, this has nothing to do with vaccines, because the "existing guidelines [are] for exposure to *methylmercury*"—and the metabolite of thimerosal is *ethylmercury*, for which "there are no existing guidelines." Furthermore, declares the FDA, "At the time of this review in 1999, the maximum cumulative exposure to mercury from vaccines in the recommended childhood immunization schedule was within acceptable limits for the methylmercury exposure guidelines set by FDA, ATSDR [Agency for Toxic Substances and Disease Registry], and WHO [World Health Organization]."¹⁹⁷

For the moment, let's overlook the FDA's guarantee that it's following the "acceptable limits" for thimerosal as set by three government agencies (and its attempt

to divert us from the issue by saying that “there are no existing guidelines” for ethylmercury). Is there indeed, as the FDA claims, a substantial difference between methylmercury (acknowledged to be toxic), and its metabolite, ethylmercury (which is considered safe, whose precursor is used in vaccines)?

A July 2015 Internet search, using the phrase “methylmercury vs. ethylmercury,” located an article in the August 2013 issue of the *Journal of Applied Toxicology*, called “Toxicity of ethylmercury (and Thimerosal): a comparison with methylmercury.” The authors review numerous *in vivo* and *in vitro* studies that show damage to cardiovascular, neural, and immune cells. Because ethylmercury has a shorter half-life than methylmercury, the authors assume that it possesses “different”—in other words, less harmful—“exposure and toxicity risks.” “In real-life scenarios,” they comment, “a simultaneous exposure to both [ethylmercury] and [methylmercury] might result in enhanced neurotoxic effects in developing mammals,” adding that “our knowledge on this subject is still incomplete, and studies are required to address the predictability of the additive or synergic toxicological effects of” both forms of mercury.¹⁹⁸ Intentional or not, this conclusion is misleading. Ethylmercury is dangerous in its own right, separate from any simultaneous exposures to methylmercury.

Many studies exist that clearly show the harm of ethylmercury and its precursor thimerosal. Here is a very small sample of studies, from the earliest to most recent. Note that the May 2010 article draws on research conducted in the 1930s and 1940s. Even then, scientists knew that thimerosal was toxic!

- ♦ October 2001: “Predicted mercury concentrations in hair from infant immunizations: cause for concern.” The abstract states: “As part of an ongoing review, the Food and Drug Administration (FDA) announced in 1999 that infants who received multiple TMS-preserved vaccines may have been exposed to cumulative Hg in excess of Federal safety guidelines. . . . Neurobehavioral alterations, especially to the more susceptible fetus and infant, are known to occur after relatively low dose exposures to organic mercury compounds. . . . Given that exposure to low levels of mercury during critical stages of development has been associated with neurological disorders in children,

If you inject thimerosal into an animal, its brain will sicken. If you apply it to living tissue, the cells die. If you put it in a Petri dish, the culture dies. Knowing these things, it would be shocking if one could inject it into an infant without causing damage.

—Robert F. Kennedy Jr.
“Deadly Immunity: Exposing the
Vaccine-Autism Link,” 2005

including ADD, learning difficulties, and speech delays, the predicted hair Hg concentration resulting from childhood immunizations is cause for concern. Based on these findings, the impact which vaccinal mercury has had on the health of American children warrants further investigation.”¹⁹⁹

- ♦ June 2005: “Mitochondrial mediated thimerosal-induced apoptosis [cell death] in a human neuroblastoma cell line (SK-N-SH).” The abstract states: “Environmental exposure to mercurials continues to be a public health issue due to their deleterious effects on immune, renal and neurological function.

Recently the safety of thimerosal, an ethyl mercury-containing preservative used in vaccines, has been questioned due to exposure of infants during immunization. Mercurials have been reported to cause apoptosis [cell death] in cultured neurons; however, the signaling pathways resulting in cell death have not been well characterized. Therefore, the

objective of this study was to identify the mode of cell death in an *in vitro* model of thimerosal-induced neurotoxicity . . . Within 2 h[ours] of thimerosal exposure (5 microM) to the human neuroblastoma cell line, . . . morphological changes, including membrane alterations and cell shrinkage, were observed. Cell viability . . . showed a time- and concentration-dependent decrease in cell survival upon thimerosal exposure. . . . These findings suggest deleterious effects . . . by thimerosal.”²⁰⁰

- ♦ May 2010: “The relative toxicity of compounds used as preservatives in vaccines and biologics.” The authors write: “The present study was specifically designed to evaluate the relative toxicities of compounds commonly used as preservatives in US licensed vaccines, to human neurons and bacterial cells. Overall, none of the compounds commonly used as preservatives can be considered ideal preservatives. They were all found to be significantly toxic to human neurons, and worse they were all found to be significantly more toxic to human neurons than [to] bacterial cells. . . . it is doubtful that any of the compounds commonly used as preservatives . . . would comply with the CFR requirements for preservatives. . . . future formulations of vaccines/biologics should be produced in aseptic manufacturing plants as single dose preparations, eliminating the need for preservatives and minimizing the risk to patients.”²⁰¹

- ◆ November 2010: “Making sense of epidemiological studies of young children exposed to thimerosal in vaccines.” The abstract bluntly states: “Since the use of TCV [thimerosal-containing vaccines] is still inevitable in many countries, this increases the need to protect vulnerable infants and promote actions that strengthen neurodevelopment. Developing countries should intensify campaigns that include breastfeeding among efforts to help prime the central nervous system to tolerate exposure to neurotoxic substances, especially thimerosal-Hg.”²⁰²
 - ◆ October 2013: “Low-dose mercury exposure in early life: relevance of thimerosal to fetuses, newborns and infants.” The abstract states: “This review explores the different aspects of constitutional factors in early life that modulate toxicokinetics and toxicodynamics of low-dose mercury resulting from acute ethylmercury (etHg) exposure in Thimerosal-containing vaccines (TCV). Major databases were searched for human and experimental studies that addressed issues related to early life exposure to TCV. It can be concluded that: a) mercury load in fetuses, neonates, and infants resulting from TCVs remains in blood of neonates and infants at sufficient concentration and for enough time to penetrate the brain and to exert a neurologic impact and a probable influence on neurodevelopment of susceptible infants; b) etHg metabolism related to neurodevelopmental delays has been demonstrated experimentally and observed in population studies; c) unlike chronic Hg exposure during pregnancy, neurodevelopmental effects caused by acute (repeated/cumulative) early life exposure to TCV-etHg remain unrecognized; and d) the uncertainty surrounding low-dose toxicity of etHg is challenging but recent evidence indicates that avoiding cumulative insults by alkyl-mercury forms (which include Thimerosal) is warranted. It is important to [not accept] . . . as ‘innocuous’ (or without consequences) the presence of a proven ‘toxic alkyl-mercury’ (etHg) at levels that have not been proven to be toxicologically safe.”²⁰³
 - ◆ December 2013: “A two-phase study evaluating the relationship between Thimerosal-containing vaccine administration and the risk for an autism spectrum disorder diagnosis in the United States.” The abstract states that even though the “etiology of ASD [Autism Spectrum Disorder] remains under debate, . . . many studies suggest toxicity, especially from mercury (Hg), in individuals diagnosed with an ASD.” The authors compare two vaccinated populations: one whose injections contained thimerosal, the other whose injections did not. “There was a significantly increased risk ratio for the incidence of ASD reported following the Thimerosal-containing DTaP [Diphtheria-Tetanus-acellular-Pertussis] vaccine in comparison to the Thimerosal-free DTaP vaccine. . . . The present study provides new epidemiological evidence supporting an association between increasing organic-Hg exposure from Thimerosal-containing childhood vaccines and the subsequent risk of an ASD diagnosis.”²⁰⁴
 - ◆ February 2014: “Acute exposure to thimerosal induces antiproliferative properties, apoptosis, and autophagy activation in human Chang conjunctival cells.” The abstract states: “Previously we have shown that acute exposure to thimerosal (Thi) can induce oxidative stress and DNA damage in a human conjunctival cell line. . . . [In this study,] DNA strand breaks were significantly increased in a dose-dependent manner with [a] 30 minute exposure to Thi [thimerosal]. . . . Acute exposure to Thi can induce DNA damage, and eventually can lead to cell death.”²⁰⁵
 - ◆ March 2014: “Mechanisms of Hg species induced toxicity in cultured human astrocytes: genotoxicity and DNA-damage response.” At concentrations generally assumed to be safe, all types of mercury cause DNA strand breakage, which interfere with the body’s ability to repair cells.²⁰⁶
 - ◆ April 2014: “In vitro study of thimerosal reactions in human whole blood and plasma surrogate samples.” The authors state: “this organomercury fragment [thimerosal] is a potent neurotoxin and is suspected to have similar toxicity and bioavailability like the methylmercury cation.”²⁰⁷
 - ◆ April 2014: “Suppression by thimerosal of ex-vivo CD4+ T cell response to influenza vaccine and induction of apoptosis in primary memory T cells.” The authors report a “proapoptotic [cell death] effect of thimerosal on human lymphocytes *at concentrations one hundred times less than those contained in the multidose vaccine*, indicating “the inhibitory effect of this preservative on T cell proliferation and functions at nanomolar [phenomenally tiny] concentrations.” [emphasis added]²⁰⁸
 - ◆ June 2014: “Thimerosal induces apoptotic [cell death] and fibrotic changes to kidney epithelial cells in vitro.”²⁰⁹
- Not all of the above studies were done *in vitro* (outside the body). The 1930s and 1940s research cited by the May 2010 article had been conducted on living beings. Yet thimerosal’s dangers have been continually trivialized, denied, and ignored by the medical establishment. Due to

Shouldering the Burden of Injections

The FDA website claims that thimerosal has “no ill effects established other than minor local reactions at the site of injection.”²¹⁰ But these “minor local reactions” of swelling and pain are not minor at all. Most vaccines are administered into the deltoid muscle of the shoulder. Sometimes, though, the material is incorrectly inoculated into the bursa—a fluid-filled sac, located deep inside the top of the shoulder, that’s designed to protect the shoulder tendons. Inoculated material that lodges inside the bursa can provoke the immune cells to attack the area. This inflammatory response results in the condition commonly called “frozen shoulder.” Some people are able to lift their arms again after awhile, but others are not so fortunate.

So many people have experienced vastly reduced range of motion in their arm after an injection, that the condition has been given a name: *shoulder injury related to vaccine administration*, or *SIRVA*. The first journal article about this phenomenon was published in 2007. In “Vaccination-related shoulder dysfunction,” the authors wrote that “the upper third of the deltoid muscle should not be used for vaccine injections, and the diagnosis of vaccination-related shoulder dysfunction should be considered in patients presenting with shoulder pain following a vaccination.”²¹¹

In 2010, the journal *Vaccine* published “Shoulder injury related to vaccine administration (SIRVA).” The authors wrote: “Common clinical characteristics include absence of a history of prior shoulder dysfunction, . . . rapid onset of pain, and limited range of motion. The proposed mechanism of injury is the unintentional injection of antigenic material into synovial tissues resulting in an immune-mediated inflammatory reaction. Careful consideration should be given to appropriate injection technique when administering intramuscular vaccinations to reduce the risk of shoulder injury.”²¹² And in 2012, the case of a 22-year-old woman “with no significant medical history” of shoulder injury was reported in the *Journal of the American Board of Family Medicine*. In an article called “A ‘needling’ problem: shoulder injury related to vaccine administration,” the authors reported “contusions on the humerus, injury of the supraspinatus, and effusion in the subacromial bursa . . . shoulder injury related to vaccine administration, likely due to injection of the influenza vaccine into the subacromial bursa.”²¹³

Since 2011, 112 people have been compensated by the US Court of Federal Claims, due to improper administration of a vaccine.

recent public outcry, the FDA finally recommended that the amount of thimerosal in vaccines be reduced, or in some cases eliminated. However, the agency still insists that “undetected” amounts (presumably existing as part of the manufacturing process) are safe. This is a blatant lie. *There are no safe levels of any type of mercury*. Not one study has ever shown that minuscule amounts of any type of mercury are safe to inject into a living being.

Aluminum. The (justified) concern over mercury may have obscured the dangers of aluminum and its compounds (hydroxide, phosphate, potassium sulfate, hydroxyphosphate sulfate). *Aluminum, a heavy metal, is a known neurotoxin that causes damage similar to, if not worse than, even mercury*. Doctors have long known of its effects: “Aluminum, a neurotoxin which affects diverse [over 200] metabolic reactions,” was published in a scientific journal in 1990.²¹⁴ Aluminum displaces trace minerals, causes cancerous tumors to grow at the injection site, protects pathogens in the blood vessels, and causes massive systemic inflammation. It’s known for causing brain damage and myriad neurological disorders: dementia, convulsions, comas, autism, Multiple Sclerosis (because it strips the myelin from nerve cells), and Parkinson’s disease. Dr. Hugh Fudenberg—considered the world’s leading immunogeneticist, as well as being an extensively quoted biologist with over 600 published scientific papers—discovered that the brains of people with Alzheimer’s, compared to those who don’t have Alzheimer’s, contain abnormally high levels of aluminum. A March 2018 study, “Aluminum in brain tissue in autism,”²¹⁵ showed that autistic children have up to ten times more aluminum in their brains than what’s considered a safe level in adults.

In 1993, doctors at the University of Paris identified a new condition they called *macrophagic myofasciitis* (MMF): microscopic lesions on the shoulder muscles that cause pain, tenderness and weakness in the muscles; joint pain; fatigue; and fever. The doctors discovered that the lesions were caused by the aluminum hydroxide in vaccines—which remains at the injection site, causing an abnormal influx of specialized immune cells called *macrophages*. Drug manufacturers say they put aluminum in vaccines because they want the immune cells to react more strongly to a virus or toxin. But injected aluminum causes the immune cells to turn on and *stay* on. This “hyper-immunity” is actually an autoimmune condition, and is responsible for the chronic fatigue present in MMF.

When ingested in food or drink, 0.2–1.5% of aluminum is absorbed. When injected, 100% of the metal is absorbed, and travels straight to the brain. (Proponents of aluminum in vaccines conveniently omit this detail.) It makes no sense to inject poison into the body.

Eye-Opening Statistics About Vaccines

Autism

- ◆ Rate of autism in the 1980s: 1 in 10,000.
- ◆ Rate of autism today: 1 in 68.
- ◆ Projected rate of autism in 2025: 1 in 2.
- ◆ Number of studies showing vaccine-autism link: 97.

Number of Vaccine Doses Recommended by the Centers for Disease Control (CDC)

- ◆ By age 6, per the 1972–1988 schedule: 23.
- ◆ By age 6, per the current schedule: 49.
- ◆ By age 18, per the current schedule: 69.
- ◆ For the 2-month baby checkup: 8.

Aluminum

- ◆ Amount of aluminum in the seven doses at the 20-month baby checkup: 1000 mcg.
- ◆ Maximum permitted amount of aluminum per day for intravenous feeding, for a healthy 8-pound baby: 18.16 mcg.
- ◆ Amount of aluminum received by fully vaccinated 18-month-old baby: 5000 mcg.
- ◆ Number of studies proving safety of injecting aluminum into human infants: 0.
- ◆ The body's need for aluminum: 0.

Mercury

- ◆ Amount in liquid waste considered toxic by the Environmental Protection Agency: 200 ppb.
- ◆ Amount in "thimerosal-free" vaccines: 2000 ppb.
- ◆ Amount in some single-dose and some infant flu shots: 25,000 ppb.
- ◆ Amount in multi-dose flu vaccines, given to pregnant women: 50,000 ppb.
- ◆ Amount that kills human neuroblastoma cells: 0.5 ppb.
- ◆ Number of mercury doses adults would receive in an average lifespan proposed in the National Adult Immunization Plan: 184.
- ◆ Increase in fetal deaths associated with mercury in the swine flu shot given to pregnant women: 4,250%.
- ◆ The body's need for mercury: 0.

Number of Various Reports to the United States VAERS (Vaccine Adverse Event Reporting System)

VAERS is a program, sponsored by the CDC and FDA, that collects data reported to it about "adverse events" (negative reactions) observed to result from vaccines. These figures were compiled in 2015.

- ◆ Life-threatening reactions after vaccinations: 7,403.
- ◆ Permanent disability after vaccinations: 7,632.
- ◆ Hospitalization after vaccinations: 28,835.
- ◆ Emergency room visits after vaccinations: 165,358.
- ◆ Deaths after vaccinations: 3,974.
- ◆ Reactions from flu shots: 93,000.
- ◆ Number of deaths following the flu shot: 1,080.
- ◆ Serious adverse reactions from the MMR (measles, mumps, rubella) vaccine since 1990: 6,962.
- ◆ Number of deaths from measles since 2004: 0.
- ◆ Serious adverse events from the Gardasil vaccine alone: 5,418.
- ◆ From 1990–2010, hospitalization rates after the number of vaccines was increased from 2 to 8: 23.5%. Mortality rates after same increase: 5.5%.²¹⁶

Money / Politics

- ◆ Total compensation to vaccine-injured children and adults 1989–2015: \$3,100,000,000.00 (3 billion, 100 million dollars).
- ◆ Percentage of claimants compensated: 20%.
- ◆ Income from vaccines, 2013 only: \$24,000,000,000.00 (24 billion dollars).
- ◆ Projected income from vaccines in the year 2025: 100,000,000,000.00 (100 billion dollars).
- ◆ Projected yearly increase in vaccine sales needed to reach projected income goal by 2025: 12.63%.
- ◆ Number of new vaccines in development (as of 2015): 271.
- ◆ Number of vaccines a child can be safely given in one day, according to Paul Offit, multi-millionaire vaccine inventor: 10,000.
- ◆ Number of current vaccines proven effective through legitimate scientific studies: 0.

History of Suppression: the Thimerosal-Autism Link

The aim of protecting the whole of society from disease through vaccination of children justified the unavoidable casualties. And making this damage public would only dissuade people from giving their children injections. . . . In truth, parents were hard-pressed to know what they were actually doing when they vaccinated their children. Vaccine monographs did not disclose complete ingredients. As ever, parents relied on doctors to explain the procedure perhaps not realizing that in the event of an adverse reaction, they and their child would get abandoned by the system they trusted and branded criminals should they ever stop vaccinating.

. . . The epidemic rise of autism parallels that of the peanut allergy in the period of its acceleration and gender ratio differences in children—more boys than girls are affected by both conditions. Many autistic children also have severe food allergies. When a link was made between vaccination and autism, the US government, vaccine makers, and the media attempted to squash it. . . .

In 2000, a confidential report *Thimerosal VSD Study, Phase I* (2000) from the CDC linked the rise in autism to a mercury based antifungal vaccine ingredient, thimerosal. Eli Lilly and Company . . . developed thimerosal in the 1930s. An emergency meeting held at the Simpsonwood Retreat Center in Georgia was called by the CDC and attended by fifty-two vaccine experts and pharmaceutical company representatives. A transcript of the meeting leaked to the Internet revealed how frightened doctors were by this government revelation. Here was the basis for ruinous class action lawsuits and serious loss of public confidence in vaccination.

While the thimerosal report ultimately was made available, its original supporting data was lost. At the same time, the database of approximately one hundred thousand children on which the report was based was given to a private company beyond the reach of the Freedom of Information Act.

In 2000, the maker of thimerosal, Eli Lilly and Company, was shielded from prosecution by parents of autistic children when House Majority Leader Dick Arney put the “Eli Lilly Protection Act” into the Homeland Security Act. When this act was repealed in 2004, US Senate Majority Leader Bill Frist in 2008 added a provision to an antiterrorism bill that denied compensation to children suffering from vaccine-related brain disorders. In a post-9/11 world, Frist explained, US companies needed protection from cumbersome and costly lawsuits so that they were free to produce vaccines in the event of a bioterrorist attack.

Despite government assurance that thimerosal would be phased out of childhood vaccines, doing so would prove difficult. . . . The public was led to believe that thimerosal had been removed from the pediatric schedule. A statement to this effect was produced by the California Department of Developmental Services and supported by the American Academy of Family Physicians. In the same statement, however, the state government admitted that trace levels existed in all vaccines and that some childhood vaccines contained original levels. They did not indicate which ones. . . . all childhood vaccines in 2009 still contained thimerosal, to one degree or another.

Since the rate of autism continued to rise despite the erroneous claim that the thimerosal was gone, the media attempted to close the case. A *Time* magazine article gave the “truth” about vaccination accusing all parents who questioned it of putting “the rest of us at risk.” The simplistic “us-versus-them” fiction boiled the discussion down into an easy-to-understand concept of personal belief versus public health. This tactic successfully drew attention away from the seminal issue of disease management and adverse events to target and ostracize a new fictitious enemy—a minority of concerned parents who believed their children had been damaged by injections.

No longer patients or even medical consumers, the parents who chose not to vaccinate their children were painted as dangerous and criminally minded people. . . .

The “us-versus-them” dialectic also drew attention away from the money. Vaccination was less about medicine than it was about economics. Pharmaceutical company CEOs must, by law, protect their shareholders first. If there was damage, they would not and could not admit it unless it was in the best interest of their company. Case in point, one pharmaceutical company CEO quoted in a 2006 article reflected that the problem with most adjuvanted vaccines was that their potency caused allergies. While his company’s brand was not as potent as others, it was safer. This unusually frank disclosure that his product caused fewer allergies was used to sell his company’s products and enhance shareholder value.

Government mass vaccinates populations to protect the economy. . . . The massive rise in chronic degenerative conditions in children has made money for investors in pharmaceutical stocks, as well.

What’s Causing It and How To Stop It* (2011)

Dangerous Chemicals

There are many chemicals in vaccines besides the heavy metals. Chemicals are so abundant in these formulas, that their levels are greater than that of the pathogens.

- ◆ *Formaldehyde (also known as formalin)*. This preservative is used to embalm corpses. The National Institute of Occupational Safety and Health (NIOSH) states that formaldehyde is “immediately dangerous to life or health” at 10 ppm (parts per million).²¹⁷ For the air inside new buildings that off-gas, the United States Environmental Protection Agency (EPA) sets an even lower limit of 0.016 ppm of formaldehyde. In contrast, flu vaccines range from 25 to 100 mcg (micrograms) per dose—comparable to 50 to 200 ppm per dose. The Material Safety Data Sheet for formaldehyde notes that it’s carcinogenic, mutagenic (able to cause genetic mutations), and possibly teratogenic (interfering with the growth and development of an embryo or fetus).
- ◆ *Gelatin*. Gelatin is a collagen-rich protein obtained by boiling bones, skin, tendons and/or ligaments, usually from cows or pigs. When eaten, gelatin is normally a healthful food (and truthfully marketed as able to help strengthen nails and hair). However, people may develop an allergy to gelatin if it’s injected with a vaccine formula instead of eaten as part of a meal. In the digestive tract, gelatin is processed correctly by the body. When injected, gelatin understandably causes the body to perceive it as a foreign invader to be eliminated. The growing epidemic of food allergies and asthma in children is partly due to the gelatin in vaccines.
- ◆ *Monosodium Glutamate (MSG)*. Commonly known as a flavor enhancer, MSG is actually a poison that in some ways mimics the effects of toxic (heavy) metals. MSG can cause abnormal blood pressure, muscle and joint pain, skin rashes, and gastrointestinal and respiratory difficulties. A neurotoxin, monosodium glutamate also damages the brain and nervous system—which is why it causes so many neurological symptoms including dizziness, migraines, insomnia, hyperactivity, mental confusion, anxiety, and depression. MSG poisoning is sometimes misdiagnosed as neurological disorders, ranging from Alzheimer’s to Amyotrophic Lateral Sclerosis (ALS, also called Lou Gehrig’s disease).
- ◆ *Phenoxyethanol*. A potent bactericide and yeast killer, this alcohol-related preservative (part of the glycol ether group) is used in perfumes, insect repellents, dyes and inks, and pharmaceuticals. The EPA’s Material Safety Data Sheets on other glycol ethers indicate that they cause genetic and chromosomal mutations, and interfere with reproduction (inducing

testicular atrophy). The FDA warns that this chemical is toxic to infants via ingestion, and “can depress the central nervous system and may cause vomiting and diarrhea.”²¹⁸ But it still allows this chemical in vaccines.

- ◆ *Polysorbate 80*. This common preservative can cause *anaphylaxis* (also known as *anaphylactic shock*)—an instant, severe, life-threatening allergic reaction involving the immune cells. Symptoms include abnormal levels of swelling that can obstruct tissues including those of the heart (leading to low blood pressure and cardiac arrest), the throat (leading to obstruction in the air passages and suffocation), and the brain (leading to a coma and eventual death). Polysorbate 80 has been used to help drugs cross the blood brain barrier; so it will also bring any vaccine pathogens into the brain. If thimerosal is in the vaccine, the Polysorbate 80 will facilitate the passage of mercury into the brain as well.
- ◆ *Triton X-100 / benzyl-polyethylene glycol tert-octylphenyl ether / oxtoxynol-10*. A detergent common in influenza inoculations. It’s used to disintegrate the virus particles and other ingredients, and prevent them from clumping or aggregating. The Material Safety Data Sheet for this chemical states that it may be harmful if swallowed or absorbed through the skin (because it gets into the bloodstream, just as it does via injection). Triton X-100 also disrupts the mitochondria (fuel burning units of the cells). Interestingly, autism and other neurodegenerative diseases are now being labeled as mitochondrial disorders.

Adjuvants, the Secret Ingredients

The main ingredient in vaccines that people usually think of is the pathogen(s) against which they’re being inoculated, and perhaps secondarily, a preservative such as thimerosal. But all vaccines contain other ingredients, some of which are truly secret, because no laws exist requiring vaccine manufacturers to disclose everything that’s in their formulas. These unlabeled substances have negatively impacted inoculated people’s lives, especially because they have no way of protecting themselves from—or preparing for possible adverse reactions to—secret ingredients.

Many unlabeled ingredients are used as adjuvants. *Adjuvant* (from the Latin word *adjuvare*, “to aid”) is a pharmacological term for a substance that modifies the effects of another material. Adjuvants are put into inoculation formulas to elicit an abnormally intense antibody response so that smaller amounts of pathogen material can be used. In addition to stimulating a stronger-than-usual immune response, sometimes an adjuvant will

cause the body to produce higher levels of one type of immune cell. For example, there may be more T cells than B cells. The CDC reassures us that adjuvants are safe, that they “help vaccines work better. . . . Vaccines often must be made with adjuvants to ensure [that] the body produces an immune response strong enough to protect the patient from the germ he or she is being vaccinated against.”²¹⁹

The most common adjuvants are aluminum hydroxide, thimerosal, paraffin (mineral) oil, egg whites, squalene (a compound found in olive and shark oils), peanut oil, and cytokines. *Cytokines* are small proteins that are naturally produced by the body, although the ones in vaccines are from external biological sources. Cytokines—normally released by cells (including immune cells) to communicate with each other—play a key role in how the body responds to infection, inflammation and trauma, steering immune cells to where they are needed. The problem is, as holistic and conventional doctors well know, too many cytokines cause major inflammation, and are prevalent in chronic degenerative conditions. Moreover, constant high levels of inflammation can lead to infection, because the swelling keeps the lymph fluid contained and thus stagnant. With insufficient circulation, wastes are not flushed from an area, providing a breeding ground for harmful microorganisms.

What happens when adjuvants made from common foods are included in vaccine formulas and injected into muscles? Because they’re injected, and injected with microbial material, *people develop allergies to the foods*. Sometimes, these allergies are so severe that they cause anaphylactic shock in susceptible individuals. *Anaphylactic shock* is a severe immune malfunction that causes severe skin reactions such as hives and unbearable itching, as well as nausea and vomiting. But the person may also suffer from swelling of the cardiovascular system and respiratory passages, which leads to heart failure, labored breathing, loss of consciousness, and even death.

For our first example, let’s address the allergy to peanuts. Prior to the use of peanut oil as an adjuvant in 1964, peanut allergies were relatively rare. Note that when I say “allergy,” I refer to more than a simple food intolerance or sensitivity: I am talking about an exaggerated, life-threatening reaction to proteins. Heather Fraser, author of *The Peanut Allergy Epidemic*, cites statistics on immune-mediated responses produced by immunoglobulins epsilon (IgE), which employs a biochemical cascade to attack the invader peanuts.

In 1997, there were about 290,000 peanut-allergic American children, a figure that doubled by 2002. In those five years, an average of 58,000 children each year became allergic to peanuts.

By 2008, the number topped one million US children. . . . it is clear through statistics, scientific inquiry, and simple anecdotal evidence (the parental refrain “no one had a peanut allergy when I was at school”) that the prevalence of the allergy among children has increased at an *alarming* rate. This development has altered the fabric of societies now forced to accommodate life-threatening allergies to a common food.²²⁰

After considering all possible reasons for the increase in peanut allergies, Fraser concludes:

Functionally, there are a limited number of ways in which a person can become anaphylactic to any substance—through ingestion, inhalation, through broken skin, and injection. And historically . . . [using the example of many people developing serum sickness as a result of penicillin injections] the only mechanism [that could be] implicated in sudden mass allergy [to peanuts] . . . was injection. Further, this period of allergy acceleration in children correlated to an unprecedented series of political, social, legal, and economic reforms directed at [increasing the number and prevalence of] vaccinations.²²¹

This conclusion is bolstered by a study, conducted in 2006 by Devi Lockwood, titled “Peanut Allergies and Vaccinations.”²²² Comparing matched groups of vaccinated and unvaccinated school-aged children, Lockwood discovered that peanut allergy was virtually nonexistent in Amish children. Not coincidentally, the Amish do not believe in vaccinations. Lockwood then researched other groups, and using statistical analysis, found that the lower rate of inoculations corresponded to fewer (or no) peanut allergies, while the higher rate of inoculations corresponded to a significant rise in peanut allergies.

In addition to stimulating the immune cells to become hypervigilant, peanut oil, which coats the vaccine antigens, slows their release into the tissues and bloodstream. The pharmaceutical companies like to use it because it stimulates the body to produce up to thirteen times more antibodies than other materials. Furthermore, the levels remain high for sustained periods, and the oil is cheap.

The authors of “Vaccine adjuvants revisited,” which appeared in a 2007 issue of *ScienceDirect*, warned:

The benefits of adjuvant incorporation into a vaccine need to be balanced against the risk of adverse side effects. Local reactions include pain, local inflammation, swelling, injection site necrosis [cell death], lymphadenopathy

[lymph node swelling], granulomas [abnormal inflammation and malfunction of immune cells], ulcers and the generation of sterile abscesses. Systemic reactions include nausea, fever, adjuvant arthritis, uveitis [eye inflammation], eosinophilia [abnormal increase in eosinophil granulocytes, a type of white blood cell], allergy, anaphylaxis, organ specific toxicity and immunotoxicity, i.e. cytokines release, immunosuppression or autoimmune diseases. Unfortunately, potent adjuvant action is often correlated with increased toxicity.”²²³

Eggs have also become a common allergen in American children. Normally, eggs are easy to digest and are rightly regarded as perfect protein. Common foods caused very few problems until scientists began including them in vaccines—either as growth media for culturing pathogens, or as adjuvants. Fraser writes that “French physiologist François Magendie (1783–1855) found that animals sensitized to egg white by injection went into shock and died after a subsequent injection.” At the start of the 20th century, “such reactions began to appear with startling frequency, particularly in children. These reactions were produced following the application of a new technology, the hypodermic syringe, to administer antitoxin sera in the revolutionary treatment called vaccination.”²²⁴

Because of adjuvants, an allergy to one substance often causes *cross-reactivity*, which can occur between apparently dissimilar proteins. It explains why, writes Fraser, “a person who is allergic to peanuts, [which are] legumes like soy and castor beans, may also react to nuts or citrus seeds, which belong to different plant families—their proteins have similar molecular weights and structures.”²²⁵

A similar situation has occurred with gelatin, which ordinarily is a nutritious food and is often added to other foods as a thickener. Gelatin allergies appeared in record numbers when drug companies began using it in vaccines along with aluminum, which sensitized people to the gelatin proteins. Negative reactions were so severe that the Japanese removed gelatin from their vaccine formulas.

Injecting normally edible proteins prevents the body from transforming them via the digestive tract. Instead, they become allergenic, traveling throughout the bloodstream and irritating the tissues. (This is what happens in a case of leaky gut, with incomplete digestion.)

Inserts that accompany vaccines warn the consumer to tell the doctor if there’s a life-threatening allergic reaction to any component of the formula. But most consumers aren’t given the inserts to read. Some are even dismissed by their doctors if they ask to read the literature. If they did, how many would allow their child to be inoculated?

Synagogue Bans Unvaccinated Children

My synagogue [in Michigan] decided that if a child does not have all of his/her vaccines, they cannot attend their preschool. . . .

I told [a Temple] employee that I could not be a member of a Temple that supported such draconian policies. The employee asked me, “Why does this affect you, your kids are older?” I stated that I do care because my patients have children and I do not feel the present vaccine program is safe . . . At this point, the executive director asked if I would meet with the Rabbi to discuss my concerns. . . .

My wife Allison and I met with [the] Rabbi . . . I told the Rabbi that following the recommended vaccine schedule exposes children to toxic doses of mercury, aluminum, and formaldehyde. Furthermore, I told him that [the] Temple’s interest should be educating . . . not mandating or opposing medical therapies. “I don’t think [this] Temple . . . should be making medical decisions for me or my children,” I stated.

The Rabbi stated that vaccines have been proven safe. . . . I said that thimerosal has never been proven to be safe to inject in any living being and that it never would be shown to be safe as it contains 50% mercury by weight. Mercury is one of the most toxic substances known . . . I informed the Rabbi that the flu vaccine contains 25,000 times the upper limit of mercury in drinking water as established by the U.S. Environmental Protection Agency.

Allison asked the Rabbi, “Why should you care whether my kids are vaccinated? If you believe in vaccines, then vaccinate your child and you don’t have to worry about my children.” . . . He did not answer.

The Rabbi said the science was settled on vaccines; they are safe and effective. I told him that simply was not true. I reminded him that the AMA and most doctors said that cigarettes did not cause lung cancer for many years. I told him that doctors said DES was safe to give to pregnant women and now, generations later, children are still being born with birth defects due to DES. I [also] reminded the Rabbi of the story of Dr. Semmelweis. In the 19th century, childbirth was associated with a high maternal mortality rate. Dr. Semmelweis proposed that the practice of a doctor washing their hands before delivering a baby reduced the mortality rate by 90%. He published his results. For that crime, [he] was thrown out the medical society and not allowed to practice medicine. . . .

If your Temple, Church, or Mosque mandates toxic vaccines, tell them you disagree and go somewhere else. It is time to get off our asses and make a stand.

The Rabies Vaccine

What Is Rabies?

Rabies, caused by the *Lyssavirus*, is known as a dangerous disease of the central nervous system that's reported to kill 55,000 people a year. The disease originated in wild and domesticated warm-blooded, fur bearing animals (bats, racoons, rabbits, coyotes, dogs, cats, horses, and other mammals). However, rabies can also affect humans who are bitten or scratched by a rabid animal, or exposed to its saliva.

The virus migrates from where it has entered the body (through a bite or infected saliva on the skin or fur), into the spinal cord and brain—where it causes inflammation (*acute encephalomyelitis*)—and then spreads to the eyes, nerve endings of the skin, and mucous membranes. As the brain is involved, both voluntary and involuntary functions are affected. Symptoms are similar in humans and animals: fever and muscle weakness, followed by anxiety and confusion, excess salivation, problems swallowing, agitation in humans and aggression in animals, respiratory failure, cardiac arrest, sometimes paralysis, and delirium, coma, and—with few exceptions, we're told—death. Symptoms can take two weeks to over one year to manifest, the average being 40 days.

The Rabies Vaccine (Shot), In Brief

Rabies Vaccine Defined. "The terms "rabies vaccine" and "rabies shot" are used interchangeably. They consist of materials intended to prevent the onset of rabies in the person or animal host. Injections against rabies are used in two situations: as a preventive vaccine, before someone has been exposed to the virus; and as a treatment shot, after someone has been exposed. The number of injections received in each situation varies.

The first rabies vaccine ingredients consisted of brain tissue from infected animals (known as the *Semple vaccine*). In developed countries, modern vaccines are sometimes produced from human or chicken embryo cells. Most inoculations, though, are made with the more plentiful brain tissue, and are most often administered in Africa, South America, and Asia. For post-exposure treatments *only*, *immune globulin* (also called *gamma globulin* or *immunoglobulin*), derived from blood plasma of rabies-infected humans, is used in addition to the brain tissue because of the antibodies it contains.

Modern medicine has no test to detect the early stages of a rabies infection. Therefore, doctors typically recommend that if a human is bitten by an animal suspected to be rabid, he or she should receive a series of treatment shots to ensure that serious symptoms do not appear.

Procedure for Humans. Human beings are inoculated both before and after exposure. After exposure, shots made of gamma globulin are injected as well as shots made from human or chick tissue.

Procedure for Animals. In most parts of the United States, the law requires owners to vaccinate pets (dogs, cats and ferrets) and livestock (cattle, sheep and horses). The Centers for Disease Control recommends that if an unvaccinated pet or livestock animal is suspected of being infected, it should be killed immediately. If the owner objects, the animal must be quarantined for six months to see if the disease appears. If symptoms do manifest, the animal is then killed. If a *pre-exposure* vaccinated animal is bitten by another animal suspected to be rabid, additional shots and quarantine are still required. This is because it's widely acknowledged that even "preventively" vaccinating an animal does not guarantee complete protection against rabies if it's exposed to the virus later.

Effects of the Rabies Vaccine

Highlights. Rabies shots are very painful. They can, and usually do, induce many symptoms reminiscent of rabies itself: swelling, headache, muscle pain, nausea and dizziness, with later symptoms of hives, fever, difficulty breathing, rapid heartbeat, and paralysis. This is just the beginning, however. The last page of this Insert provides a small sample of articles (all published in respected medical journals) whose titles indicate additional severe damage to humans and animals who received the rabies vaccine. For now, let's look at some other details.

What the Rabies Vaccine Actually Does (to Humans). There's quite a bit of research on the damage to human beings from the rabies vaccine. Studies have been published in (among other languages) Chinese, French, German, Hungarian, Italian, Polish, Portuguese, Russian, and Turkish. As long ago as 1975,²²⁶ and later in 1984²²⁷ and 1990,²²⁸ the *Journal of the Neurological Sciences* published studies, all of which showed similar damning results. The damage included inflammation of the brain and nerve tissue, infections of the central nervous system, and degeneration of the spinal cord—which itself caused a variety of symptoms, including seizures and partial paralysis. In one study, 14 of the vaccine recipients died.

In 1983, "Delayed onset of post-rabies vaccination encephalitis" appeared in *Annals of Neurology*. The authors wrote: "A 31-year-old veterinarian developed seizures, left [-sided] hemiparesis [weakness], loss of memory, and behavioral disorders 5 months after intensive antirabies vaccination . . . [He also grew a]

mass that extended to the left frontal lobe through the corpus callosum. Brain biopsy showed foci [differently-appearing cells] of primary demyelination [nerve cell sheath destruction] largely confined to the white matter. The lesions were characteristic of the demyelinating encephalomyelitis that follows treatment with certain vaccines against rabies. The hemiplegia improved, but seizures, memory impairment, and abnormal behavior persisted.”²²⁹

A 2003 article, “Neurological Complications of Rabies Vaccines,” stated: “Developing countries continue to use the neural tissue rabies vaccines despite the high frequency of serious neurological complications such as encephalitis, encephalomyelitis, myeloradiculitis and polyradiculitis. . . . The pathogenesis involves demyelination occurring due to an autoimmune reaction against myelin, triggered by the vaccine. All of our cases demonstrated lesions of demyelination in various parts of the nervous system.”²³⁰

In 2008, the well-known medical term, ADEM, was discussed in “Post-vaccination encephalomyelitis: Literature review and illustrative case.” An acronym for *Acute Disseminated Encephalomyelitis*, ADEM is “an inflammatory demyelinating disease of the central nervous system . . . associated with several vaccines such as rabies, diphtheria–tetanus–polio, smallpox, measles, mumps, rubella, Japanese B encephalitis, pertussis, influenza, hepatitis B, and the Hog vaccine. We review ADEM with particular emphasis on vaccination as the precipitating factor.”²³¹ A whopping 35% of the study subjects developed Multiple Sclerosis after being inoculated, and one man suffered optic nerve atrophy (four weeks after receiving an influenza shot.) Not everyone recovered. The vaccines contained both “inactivated” and “live” viruses. The article, “Possible Interactions Between Rabies Vaccination and a Progressive Degenerative CNS Disease,” referred to many cases of a Multiple Sclerosis-like condition appearing from 2 to 20 years after subjects received a presumably preventive rabies vaccine (although it can also take only weeks for symptoms to appear). The authors described “similarities between postvaccinal encephalomyelitis and the progressive form of multiple sclerosis.”²³²

What about effects from inoculation material that’s *not* made from brain tissue? Gamma globulin by itself can increase the risk of blood clots. As described in “Side-effects of intravenous immune globulins,” from a 1994 edition of *Clinical and Experimental Immunology*, more effects include “headache, myalgia [muscle ache], fever, chills, low back pain, nausea and/or vomiting; vasomotor and cardiovascular manifestations marked by changes in blood pressure and tachycardia—these may be related to occasional reports of shortness of breath and chest tightness. These reactions are generally

considered to be due to aggregated immunoglobulin molecules which cause the complement system to be activated. They may be due to antigen-antibody reactions as well . . .”²³³ In other words, boosting the immune cells into overdrive—which is what vaccines are designed to do—produces hyperactive responses in the entire body. This hyperactivity has also been recorded as anaphylactic reactions, neurological complications, kidney failure, and fatal strokes.

What the Rabies Vaccine Actually Does (to Dogs and Other Animals). In the United States, rabies vaccines for pets has spawned a very lucrative business. Each shot costs about a dollar to make, but the markup ranges from ten to one hundred times that amount (and there’s an even greater markup during the first year of inoculation). In the US, if dog owners don’t comply with a law that forces them to regularly vaccinate their (registered) pets, they’re fined, and the animal might be taken from them. Such laws ensure a steady income for vets and drug companies. It’s a rare veterinarian who’s willing to work with an unvaccinated animal.

Based on the number of published studies on the “side” effects of rabies vaccines, it’s clear—to both the drug industry and physicians—that the rabies vaccine causes significant increase of encephalomyelitis (brain inflammation), the eroding of myelin from the nerve sheaths, and related autoimmune inflammatory diseases (to name just a few conditions). The damage suffered by rabies-vaccinated pets is extensive, and almost identical to the harm experienced by humans. Human owners and veterinarians commonly notice that the animals suffer joint pain, muscle aches, diarrhea, vomiting, skin eruptions, and convulsions. Sometimes they die.

Rabies-vaccinated dogs frequently undergo personality changes. They may become excessively reactive, phobic, and hyper-aggressive. Or they might become timid. They exhibit behaviors that most of us believe are “normal” (albeit neurotic) because we don’t have experience with dogs who *haven’t* been vaccinated. There may be excessive licking, violent itching with no apparent cause, or reverse sneezing or gagging (spasms of the larynx). Many owners notice obsessive-compulsive behaviors such as tail chasing, fly biting, or insisting on fetching a ball to the point of exhaustion. The animal may also bark, growl or lunge, even committing unprovoked attacks (reminiscent of a rabid dog). Veterinarian Richard Pitcairn calls it the rabies *miasm*, which he defines as “a chronic disturbance unrecognized, except as it’s manifested by acute flareups of what seem to be individual diseases.” The dogs “become more aggressive, more likely to bite, more nervous and suspicious. They may also have a tendency to run away, to wander, and also sometimes to have excessive saliva, and to tear things up. It’s not that they

have rabies, but they seem to express some symptoms of the disease from exposure to the vaccine.”²³⁴ It’s not surprising that formerly joyful, affectionate pets are now irritable, fearful and snappy: the brain and nerve tissues are constantly being irritated due to chronic infection and inflammation, which naturally leads to a hypersensitivity of all the senses. Might the animals also be cranky because they’re in pain? Essentially, the pet is suffering from a sub-clinical case of rabies!

The allopathic veterinary community is well aware of the damage and even fatalities that rabies vaccines can cause. In 2008, “Postmarketing surveillance of rabies vaccines for dogs to evaluate safety and efficacy,” which appeared in the *Journal of the American Veterinary Medical Association*, analyzed such data from reports from April 1, 2004, through March 31, 2007. Information was received from “multiple sources,” which included reports that pet owners voluntarily sent to the Center for Veterinary Biologics (CVB). Note that not all pet owners report vaccine injury because they aren’t aware that injuries might be (or are) vaccine-related. Or, they don’t know who to contact. Or, if the animal becomes very sick or dies, they might feel too dispirited to report, even if they knew that the damage was caused by vaccines and knew where to send their findings. Here’s a summary of *reported* damage, from the highest to the lowest percentage. Note that death is not the lowest.

- ◆ Vomiting: 28.1%
- ◆ Facial swelling: 26.3%
- ◆ Injection site swelling or lump: 19.4%
- ◆ Lethargy: 12.0%
- ◆ Urticaria (hives): 10.1%
- ◆ Circulatory shock: 8.3%
- ◆ Injection site pain: 7.4%
- ◆ Pruritis (anal itching): 7.4%
- ◆ Injection site alopecia or hair loss: 6.9%
- ◆ Lack of consciousness: 5.5%
- ◆ Death: 5.5%
- ◆ Diarrhea: 4.6%
- ◆ Fever: 4.1%
- ◆ Anaphylaxis: 2.8%
- ◆ Ataxias (lack of muscle coordination): 2.8%
- ◆ Lameness: 2.8%
- ◆ General signs of pain: 2.3%
- ◆ Hyperactivity: 2.3%
- ◆ Injection site scab or crust: 2.3%
- ◆ Muscle tremor: 2.3%
- ◆ Tachycardia (rapid heartbeat): 2.3%
- ◆ Thrombocytopenia (low blood platelet count): 2.3%

The article authors remark, “Rabies vaccines are the most common group of biological products identified in adverse event reports received by the CVB.”²³⁵

Dogs are injured even more by being inoculated before eight weeks of age, when their immune response is weak and immature. Most are injected many times. A 6-pound Chihuahua receives the same amount as a 60-pound Golden Retriever. One widely-used veterinary textbook, *Kirk’s Current Veterinary Therapy*, bluntly states that annual revaccinations “lack scientific validity or verification. . . . There is no immunological requirement for annual vaccinations. Immunity to viruses persists for years or for the life of the animal.”²³⁶ It’s even questionable whether any vaccines are warranted. This will be discussed shortly.

The public is continually told that inoculating the animal will make it immune to the rabies virus. If the animal then bites someone, it is rationalized, there’s no danger that the bite recipient will contract rabies, because there won’t be any infection to spread. But, as some of the previously cited research explicitly states—and as even many pro-vaccine organizations know—this is an outright lie.

The Problem (?) Is, Not Everyone Dies From Rabies

Many variables determine how quickly (and whether or not) someone will succumb to an infection: the numbers of harmful microbes that are transmitted, how well the immune response is functioning, the severity and location of the bite, and—in the case of rabies—the strain of pathogen. (Dogs and bats carry slightly different varieties of the *Lyssavirus*.) If the rabies virus is introduced at a limb instead of at the face, neck, or other area close to the spine, the infection will travel to the brain more slowly, thus offering more time, and hence more of a chance, for a successful treatment.

Some people bitten by rabid animals can live normally even if they do not receive treatment. In the last decade, the mainstream press has reported the miracle of people who exceeded doctors’ expectations by surviving rabies. For instance, in early 2009, a 17-year-old girl was admitted to a Texas hospital and diagnosed with rabies antibodies in her blood, but no viral RNA in her saliva or tissues. She was released in good health. Some doctors later disputed that she ever had rabies; most believe that infected individuals always die. But it’s worth noting that because the girl was a runaway, she’d been camping in a cave—a place known to harbor bats, which can carry rabies. The girl had a strong immune response, which accounted for the high levels of rabies antibodies but no actual *Lyssavirus* in her system.

We can also learn a great deal by examining entire groups of people. An 2012 article, “Evidence of Rabies Virus Exposure among Humans in the Peruvian Amazon,”

describes resistance to the rabies virus among people living in the Amazon rainforest in Peru, a region heavily populated by vampire bats. All of the survivors are from communities that lack formal roads and adequate housing. One village is a two-hour boat ride from the nearest health clinic, and the other village is six hours from the nearest doctor. The authors write: "There is ample evidence of frequent depredation [damage] by vampire bats on humans and livestock . . . Risk factors for bat exposure included [people of an] age less than or equal to 25 years and owning animals that had been bitten by bats. Rabies virus neutralizing antibodies (rVNAs) were detected in 11% (7 of 63) of human sera [fluids] tested."²³⁷ Simply stated, about 1 in 7 people in these Peruvian Amazon villages are resistant to rabies.

Skeptics might dismiss this study because the bite from a vampire bat is mild compared to a bite from a dog or racoon. But even this advantage (which some might use to discredit the study) provides valuable clues. Dr. Charles Rupprecht, a co-author of the study, states that the blood of other human populations—such as 1% of racoon hunters—also tests positive for rabies antibodies. Dr. Amy Gilbert, another co-author of the study, points out that non-fatal exposure to the *Lyssavirus* may occur more often than people expect, because "unless people have clinical symptoms of the disease, they may not go to the hospital or clinic. . . . We all still agree that nearly everyone who is found to be experiencing clinical symptoms of rabies dies. . . . But we may be missing cases from isolated high-risk areas where people are exposed to rabies virus and, for whatever reason, they don't develop disease."²³⁸ Gilbert's "for whatever reason" is what the natural health field has always understood: that prolonged, relatively mild exposure strengthens the immune response.

Animal resistance follows a similar pattern. Henry Wilde, a physician in Bangkok, Thailand, says: "There are survivors [of rabies]. Fourteen percent of dogs survive. Bats survive."²³⁹ *New Scientist* agrees: "Researchers have known for years that some animals in the wild and in the lab survive rabies all on their own. . . . Rabies may not be the invincible killer we thought."²⁴⁰ *The presence of antibodies indicates exposure to the virus without one necessarily becoming seriously ill.*

It's difficult to accurately estimate how many people have contracted rabies and lived. Mainstream media, which feeds on sensationalism, likes to tell of the few heroic survivors (and the doctors who save them). But if people who are routinely exposed—and calmly continue on with their lives—aren't generally investigated or reported, how would we even know they exist?

What about rabies death statistics? Shouldn't all dogs be routinely vaccinated, anyway—just in case? To get a different perspective, let's look at some figures

from *Dogs Naturally* magazine. The author compares casualties from rabies to other life-threatening events. Here are various causes of death in the USA, on an average yearly basis:

- ◆ Number of people killed by lightning strikes: 90.
- ◆ Deaths from dog attacks (not rabies-related): 15–25.
- ◆ Deathly accidents from deer on roads: 200.
- ◆ Deaths from car accidents: 27,000.
- ◆ Death by murder from men (women who murder are only one-third as plentiful as men): 32,000.
- ◆ Death by influenza or pneumonia, in people older than 91 years: 3,300

Now here's an overview of all the known deaths from rabies for one year, in the US and Europe combined:

- ◆ 5 deaths from rabies, but none from dog bites.

*The fact is, there have been no rabies deaths due to a dog bite in the last 30 years.*²⁴¹ Given the harm of the rabies vaccine, is it really necessary to vaccinate dogs?

The Problem of Diagnosing Rabies

With so many negative effects from the rabies vaccine, it's a good idea to find out if a human or animal even *has* rabies before administering an inoculation that itself could cause irreparable damage or even prove fatal. How is rabies diagnosed?

Researchers who have examined the brains, spinal nerves, and nerve cell plasma of rabies-infected individuals have discovered small biological structures called *Negri corpuscles* (or *Negri bodies*). They state that these structures prove the presence of the rabies virus. But they also claim that an absence of Negri bodies does *not* necessarily mean the absence of rabies! How can both be true? Other physicians have discovered that Negri bodies appear in individuals who are *not* diagnosed with rabies. Still other scientists state that Negri bodies are indistinguishable from the *Lentz-Sinigallia* corpuscle, which exists in dogs with distemper. In the 1960s, American veterinarian John A. McLaughlin performed autopsies on dogs thought to have died of rabies, and found no evidence at all of Negri corpuscles. He wondered if this infection, which everyone called rabies, was actually another disease.

Ultimately, this double talk about the rabies diagnosis makes some wonder whether the disease even exists.

In some cases, identifying the pathogen is helpful—even necessary—so the infected individual can be properly treated. However, many natural substances are antiviral, antibacterial *and* antifungal, and at the same time they support immunity. So you don't need to know exactly what pathogen you're treating.

The Problem of Treating Rabies

Conventional medicine continually reminds us that rabies has no cure—hence, the repeated need for pre-exposure vaccines. But new research from the US (now being duplicated in several countries) says otherwise. The brain, says Dr. Bernhard Dietzschold, *can* recover, even after being exposed to the *Lyssavirus*! “The dogma has always been that when the rabies virus reaches the brain there is no hope for recovery. . . . We have shown in animal models that this is not right—the immune system can clear the virus from the central nervous system.”²⁴² This ability was reported in 2009, in “Effective preexposure and postexposure prophylaxis of rabies with a highly attenuated recombinant rabies virus.”²⁴³ The mice in the study were able to eliminate rabies from the brain, spinal cord and nerves for two reasons. One, different strains of rabies appear to affect the body differently. Virulent strains of rabies hide from the immune cells, but weaker strains cannot—probably because they contain more *glycoproteins*, tiny surface molecules that make them more visible to the immune B cells and T cells, and allow antibodies to adhere to them. Two, conventional pre- and post-infection rabies vaccines for people use small bits of dead viruses, which cause harmful inflammation and can’t help the body clear the *Lyssavirus* from the central nervous system. When Dietzschold and his colleague D. Craig Hooper gave infected mice a *weaker, live strain of the rabies virus*, the mice were able to eliminate all of the infection:

Because of their ability to induce strong innate and adaptive immune responses capable of clearing the infection from the CNS [central nervous system] after a single immunization, live-attenuated rabies virus (RV) vaccines could be particularly useful not only for the global eradication of canine rabies *but also for late-stage rabies postexposure prophylaxis of humans*. To overcome concerns regarding the safety of live-attenuated RV vaccines, we developed the highly attenuated triple RV G [rabies virus glycoprotein] variant . . . [which] is completely nonpathogenic after intracranial infection of mice that are either developmentally immunocompromised . . . or have inherited deficits in immune function . . . In contrast to wildlife RVs, most attenuated RV strains [created in the lab] replicate very quickly and express large amounts of G [glycoproteins], thereby inducing strong adaptive immune responses that result in virus clearance. These properties provide the basis for the use of attenuated RV strains for the pre- and PEP [postexposure prophylaxis] of rabies. [emphasis added]²⁴⁴

A Proposed Better Rabies Vaccine (Maybe)

By definition, vaccines force the immune cells to exceed normal and healthy limits, thus sabotaging their proper function. Pieces of pathogens are counterproductive to the presumed intent of vaccines. So are adjuvants (such as heavy metals and mineral oil). They don’t belong in the tissues and were never meant to be injected. Acting like poisons, they don’t allow immune cells to *safely* recognize and tag a pathogen for elimination.

Modern medicine likes to manipulate and alter the body’s natural responses, rather than encourage its innate ability to heal. Most physicians don’t respect (if indeed they ever recognized) that the body is generally capable of protecting itself against infectious disease as long as it has the raw materials that it needs, and has not been overly damaged by the invasion of too many noxious agents (whether via ingestion, inhalation, application or injection). Humans and animals are unnecessarily vaccinated for many diseases which they could either naturally combat or from which they could easily recover. Sometimes, a vaccine suppresses the pathogen, which simply allows a more virulent version of the disease to appear later. One example is the chicken pox vaccine. An inoculated child may experience the much more serious shingles—a nastier form of chicken pox—as an adult.

It’s worth wondering if the *Lyssavirus* is an exception to the “Do not vaccinate” edict. There is a low incidence of rabies deaths worldwide compared to other diseases, but most strains of rabies cause an excruciating and painful death. Therefore, a rabies vaccine *might* prove beneficial, but *only* under the following circumstances:

- ◆ Use only the weakest strains of *live Lyssavirus*, as prepared by Hooper and Dietzschold—if, that is, it’s truly safe as the authors claim, with no “side” effects.
- ◆ Administer the vaccine *only after* exposure to the rabies virus, *never before*.
- ◆ Never use heavy metals, adjuvants, or other fillers—only a necessary carrier solution, such as saline.
- ◆ Simultaneously administer natural immune boosters, such as colostrum (or its extract of polypeptides, a.k.a. transfer factors), and one or more germicidal herbs such as echinacea, olive leaf extract, neem, teasel, cat’s claw, or chaparral.
- ◆ Routinely use ozone, which disables pathogens very effectively. Ozone can be administered both intravenously and via ear insufflation, a route allowing it to easily reach the brain. (See Chapter 3, **Oxygen Therapies**.)
- ◆ If necessary, sedate the individual to protect the brain, while the immune cells are working to eliminate the infection. (This may be more appropriate for humans than animals.)

Vets Against Vaccines

Conscientious veterinarians are opposing vaccines, despite the rabies phobia and mandatory vaccination laws. It's time to rely on sound science, rather than capitulate to pharmaceutical industry propaganda and lawmakers who are causing so many animals to suffer.

- ◆ How often has a pet been brought into our clinic with a history of telltale symptoms: fever, stiff or painful joints, lethargy, or lack of appetite, as if the pet had the flu, but it's not the flu. "Did your dog, by any chance, get vaccinated several days before this started," I'll ask. The owner will look at me as if I'm a mind reader.

—*Martin Goldstein, DVM (South Salem, New York, US)*

- ◆ Every skin problem . . . is due to vaccinations without fail. Later in life, arthritic situations and degenerative spinal dis-eases are the result of vaccines. The rabies vaccine in dogs and cats causes so many problems it isn't funny . . . personality changes, skin changes, damage to the thyroid and endocrine systems. It lowers the immune system tremendously. The animal becomes fair game to just about any disease.

—*John Fudens, DVM (Boise, Idaho, US)*

- ◆ One of the saddest things in our practice is to restore a dog's health (sometimes after prolonged and careful work) only to have the animal suffer a relapse and go into a decline after we acquiesce to a required rabies vaccine.

—*Richard Pitcairn, DVM (retired, US author)*

- ◆ Vaccinosis is the reaction from common inoculations (vaccines) against the body's immune system and general well being. These reactions might take months or years to show up and will cause undue harm to future generations.

—*Dr. Pedro Rivera, DVM (Sturtevant, Wisconsin, US)*

- ◆ The first thing that must change with routine vaccinations is the myth that vaccines are not harmful. . . . Veterinarians and animal guardians have to come to realize that they are not protecting animals from disease by annual vaccinations, but in fact, are destroying the health and immune systems of these same animals they love and care for.

—*Charles Loops, DVM (Pittsboro, North Carolina, US)*

- ◆ A growing number of holistic and now even conventional veterinarians are convinced, from sad experience, that vaccines . . . are doing more harm than good. I myself think that's a conservative view. I think that vaccines, justly credited as the tamers of disease epidemics, are nevertheless the leading killers of dogs and cats in America today.

—*Martin Goldstein, DVM (South Salem, New York, US)*

- ◆ . . . The hyena dog . . . was in 1989 threatened with extinction. Scientists vaccinated individual animals to protect them against rabies but more than a dozen packs then died within a year—of rabies. This happened even in areas where rabies had never been seen before. When researchers tried using a non-infectious form of the pathogen (to prevent the deaths of the remaining animals) all members of seven packs of dogs disappeared. And yet the rabies vaccine is now compulsory in many parts of the world. Is it not possible that it is the vaccine which is keeping this disease alive?

—*Vernon Coleman, MB (England)*

- ◆ Injected vaccines bypass normal defenses. They implant mutated microorganisms, preservatives, foreign animal proteins and other compounds directly into the system. This is done in the name of preventing a few syndromes. If an animal is in an optimal state of health, he or she will produce the strongest immune response possible. This response offers protection against all natural challenges. The irony is that vaccine labels say they are to be given only to healthy animals. If they were truly healthy, they would not need them.

—*Dr. Russell Swift, DVM (Ft. Lauderdale, Florida, US)*

- ◆ I would have animals all over the country responding beautifully to holistic treatment for one cancer or another. Then I'd get panicked calls. A tumor had just appeared. Or with those who'd had tumors removed, the tumor was back, worse than before. I'd ask the owner, "What in the dog's environment changed?" "Nothing." "Did you put him back on commercial pet food? Stop giving him supplements?" "Nope. In fact," the owner would say, "our local veterinarian told us just two weeks ago how great our dog was doing when we brought him in for his annual vaccines!"

—*Martin Goldstein, DVM (South Salem, New York, US)*

- ◆ Perhaps we have not eliminated the acute diseases at all, but merely changed their form into a chronic state of the acute disease. Prior to vaccination, the acute diseases were certainly life threatening, but once puberty was reached, most individuals live a long, relatively disease-free life. Today most individuals survive or bypass the acute phase, but they (we) live relatively disease-ridden lives. Vaccinations may prevent acute diseases, but if the exchange is for a lifetime of chronic disease, is that a viable option? . . . Will the patient live and flourish, or simply exist?

Disabling the Immune Response

The medical establishment claims that vaccines help the body develop immunity, but vaccines more typically cause either a lethargic or a hypervigilant response. To review, vaccines disable immune function because:

- ◆ The pathogens in the inoculation formulas are so altered, they often become part of the body's innate genetic material. This causes the body's immune cells to ignore similar pathogens, or attack its own tissues.
- ◆ The foreign materials are introduced into the body via injection. Normally, foreign material gets into the body through the mucous membranes, which act as a natural barrier to protect the body from foreign substances (everything that is "not-body"). The body responds to foreign irritants by expelling them in the same manner in which they arrived—via vomiting, or coughing and sneezing via the mucous membranes. Although the system is designed to eliminate viruses and other harmful microbes efficiently, vaccinations, as Van Beveren points out, bypass the body's "carefully designed evolutionary system by introducing toxic matter directly into the bloodstream. This gives the body no warning, . . . no chance to recognize . . . or defend itself against future challenges from typical antigens [foreign irritants]." ²⁸⁶ Allopathic medicine, by classifying these items as medical ingredients under the term "immunization," makes it seem normal and appropriate to inject poisons into the bloodstream.
- ◆ The ingredients comprising the formulas are harmful. The combination of manipulated pathogens, diseased biological tissues from various sources, mercury and aluminum compounds, an extra load of inflammatory proteins (cytokines), and various foods that act as irritants, do not promote health.

What Really Contributed to Better Health

Proponents of vaccines always cite the improved health of people who are vaccinated. This is not true, and in a moment I will dispute this claim with reliable data. In the meantime, let's take a brief look at other factors that were actually responsible for the improvement in public health. What helped people resist disease, if it wasn't inoculations?

Improved Living Conditions

History shows us that when serious diseases decreased, it was not due to the availability of vaccinations, but to the following:

- ◆ The introduction of indoor plumbing, which resulted in improved sanitation.
- ◆ Better protection from the elements, such as sturdier housing and more adequate clothing.
- ◆ Uncontaminated water for drinking and bathing.
- ◆ Cleaner food handling and storage.

Even today, some poorer countries don't have readily available, clean drinking water. Nor do they have the advanced sanitation facilities that wealthier nations enjoy. Thus, many people in underdeveloped parts of the world suffer from debilitating and life-threatening diseases such as trachoma and snail fever. But the solution is more basic than inoculations. Hundreds of thousands of deaths could be prevented if people had a cleaner living environment. The health of these developing nations would also markedly improve if their citizens had enough high quality food to eat. With better living conditions worldwide, and not just in the wealthier countries, the "need" for vaccinations and toxic medications would decrease.

Even though the United States is a highly developed nation in some ways, its population is sicker than residents of many poorer countries. People rely on drugs rather than prevention, thanks to an atrocious diet of fast food, sugars, fake fats, artificial preservatives, and chemical additives. Plants, raised on depleted and contaminated soil, are riddled with pesticides and herbicides (as are the animals that eat them)—especially if they're grown from seeds that are genetically engineered. (This is discussed in detail in Chapter 3.)

Lying with Statistics

Statistics are not the objective, static data we are led to believe; any data can be used to substantiate lies. In 1954, Darrell Huff wrote the humorous, easy-to-understand *How To Lie With Statistics* which quickly became a classic. Lying with statistics is unfortunately the norm—and it occurs even more today than when Huff's little volume was written. It's beyond the scope of this book to discuss in detail the ways in which statistics can be mathematically manipulated, but here are just a few examples of statistics manipulation as it relates to claims of medical success.

- ◆ *Take small improvements and make them seem more significant than they really are.* If you compare vaccinated people to a cross-section of the general population, you may find that they suffer equally from ill health. You may also find that the vaccinated are just as likely as the unvaccinated to contract the disease against which they've been inoculated. But if you compare vaccinated people to a specially selected

Dr. Russell Blaylock Interviewed: The Effect of Vaccines on the Physiology and Biochemistry of the Brain

Russell Blaylock, MD, is a board certified neurosurgeon, lecturer, and author who owns a nutritional practice. He practiced conventional medicine for 25 years before pursuing his nutritional studies and research full time.

It seems the brain is always neglected when pharmacologists consider side effects of various drugs. The same is true for vaccinations. For a long time no one considered the effect of repeated vaccinations on the brain. This was based on a mistaken conclusion that the brain was protected from immune activation by its special protective gateway called the blood-brain barrier. More recent studies have shown that immune cells can enter the brain directly, and more importantly, the brain's own special immune system can be activated by vaccination.

You see, the brain has a special immune system that operates through a unique type of cell called a microglia. These tiny cells are scattered throughout the brain, lying dormant waiting to be activated. In fact, they are activated by many stimuli and are quite easy to activate. For our discussion, activation of the body's immune system by vaccination is a most important stimuli for activation of brain microglia.

Numerous studies have shown that when the body's immune system is activated, the brain's immune cells are likewise activated. This occurs by several pathways, not important to this discussion. The more powerfully the body's immune system is stimulated the more intense is the brain's reaction. Prolonged activation of the body's immune system likewise produces prolonged activation of the brain's immune system.

Therein lies the danger of our present vaccine policy.

The American Academy of Pediatrics and the American Academy of Family Practice have both endorsed a growing list of vaccines for children, even newborns, as well as yearly flu shots for both children and adults. Children are receiving as many as 22 inoculations before attending school.

The brain's immune system cells, once activated, begin to move about the nervous system, secreting numerous immune chemicals (called cytokines and chemokines) and pouring out an enormous amount of free radicals in an effort to kill invading organisms. The problem is—there are no invading organisms. It has been tricked by the vaccine into believing there are.

Unlike the body's immune system, the microglia also secrete two other chemicals that are very destructive

of brain cells and their connecting processes. These chemicals, glutamate and quinolinic acid, are called excitotoxins. They also dramatically increase free radical generation in the brain. Studies of patients have shown that levels of these two excitotoxins can rise to very dangerous levels in the brain following viral and bacterial infections of the brain. High quinolinic acid levels in the brain are thought to be the cause of the dementia seen with HIV infection.

The problem with our present vaccine policy is that so many vaccines are being given so close together and over such a long period that the brain's immune system is constantly activated. This has been shown experimentally in numerous studies. This means that the brain will be exposed to large amounts of the excitotoxins as well as the immune cytokines over the same period.

Studies on all of these disorders, even in autism, have shown high levels of immune cytokines and excitotoxins in the nervous system. These destructive chemicals, as well as the free radicals they generate, are diffused throughout the nervous system doing damage, a process called bystander injury. It's sort of like throwing a bomb in a crowd. Not only will some be killed directly by the blast, but those far out into the radius of the explosion will be killed by shrapnel.

Normally, the brain's immune system, like the body's, activates quickly and then promptly shuts off to minimize the bystander damage. Vaccination won't let the microglia shut down. In the developing brain, this can lead to language problems, behavioral dysfunction, and even dementia. In the adult, it can lead to the Gulf War Syndrome or one of the more common neurodegenerative diseases, such as Parkinson's disease, Alzheimer's dementia, or Lou Gehrig's disease (ALS) [Amyotrophic Lateral Sclerosis].

population that's exceptionally ill, the vaccinated can be made to seem healthier than they actually are. Drug companies are not legally obligated to reveal what groups they are using when they make comparisons.

- ◆ *Use a group that you have carefully screened for certain characteristics that will yield the results you want.* Rather than choose a random vaccinated group that represents the general population, select a group of test subjects you know will respond favorably, so you can prove that vaccines are successful. Pick people who were vaccinated, but who (within the time frame of the study) don't get the disease for which they were inoculated, and don't become ill from any other disease either. This leads us to the next strategy.
- ◆ *Control the amount of time that you are allocating to the study.* Damage by vaccines to one's immune function and other systems can build up over time. If you monitor your test subjects for only a brief period, long-range ill effects are much less likely to occur—and thus you won't have to record them. Conducting a study over a very brief period will almost certainly help you produce the outcome you want.
- ◆ *Don't report subsequent declines in health of vaccinated subjects.* A vaccine is assumed to be successful if it suppresses visible symptoms of the disease for which it has been taken. But if a recently inoculated subject becomes ill due to an apparently unrelated disease, it doesn't have to be reported because it's assumed that a vaccine is incapable of causing any disease.
- ◆ *Rename a disease to disguise the fact that an outbreak of that disease has been caused by a vaccine.* If thousands of people are inoculated against a particular disease, and then (in response) there's a more potent than usual epidemic—of that very same condition—change the name of the disease to hide the relationship between the vaccine and the outbreak. Let's say that people are inoculated against Disease X, and then the incidences of Disease X increase. When reporting the outbreak, simply change the name of Disease X to Disease Y. This way, it will appear that the vaccination has been a success—and it's just a coincidence that there has been an outbreak of some other disease so soon after a mass inoculation. (As we shall see shortly, this happens quite a bit, especially with the polio vaccine.)
- ◆ *If a study doesn't prove what you want it to, throw it out and pretend it never existed.* Then the public will never know about studies showing the failure rate of vaccines.

- ◆ *Outright lie: Claim that a particular vaccine is effective when it's not.* Earlier in this chapter, I mentioned the 2005 study by Greek physician John Ioannidis, whose statistical analysis showed that published data is more than 50% false.

There are many ways to lie with statistics. Most people don't think to question how, or if, the data has been manipulated.

Inoculation Criminals and Cover-Ups

So far, I have focused on the history of vaccinations, how inoculation ingredients affect the body, and the conditions catalyzed or caused by vaccines. Now it's time to discuss those who are aware of the damage but continue to promote these dangerous drugs anyway. What follows are brief descriptions of a small sample of politically-motivated cover-ups, along with legislation that has forced poisons into people under the guise of helping. Events are summarized from the past to the most recent.

More attempts than ever are being made to control the world's population through drugs, so it's important that you remain informed of current developments. For excellent online and printed sources of information, see Appendix A for many organizations related to health, food, politics, vaccines, and more.

Polio from Vaccine in the US (1950s)

In the 1950s a vaccination program for polio was implemented, causing clusters of a polio epidemic afterward. But the CDC (Centers for Disease Control, formerly the US Public Health Service) disguised the number of inoculation-related outbreaks by manipulating statistics: it called polio by another name. "In nearly every state where the Salk vaccine was administered," Van Beveren reminds us, "the polio rate leaped by 400% to 600%," to which the Public Health Service responded by issuing "new guidelines for the diagnosis of the disease. From statistics we note that polio ceased to be a big problem almost immediately [after inoculation] but that suddenly aseptic or viral meningitis (sometimes spinal meningitis or Multiple Sclerosis) were seen in epidemic proportions in approximately the same number that polio was diagnosed in prior years. . . . In *Archives of Pediatrics* (1950), Dr. Ralph Scoby lists not less than 170 diseases with 'polio-like symptoms and effects, but with different names. . . . Little mention is made of the fact that polio disappeared in Europe without mass immunization, and of the 25 or so cases of polio that have turned up in the past few years, virtually all were vaccine-induced.'" ²⁸⁷

Vaccine Makers Granted Immunity (1986)

In the US, if a product is dangerous, buyers are usually compensated for damages. For instance, car manufacturers don't always produce a safe car: they might conceal data about a faulty switch that claims lives. But the government forces them to do the right thing. Automobiles are recalled, the manufacturers are fined, and motorists are able to sue, often receiving monetary compensation.

Unfortunately, consumers' right to be compensated due to dangerous products doesn't apply in the world of Big Pharma. In 1986, the US Congress created the Vaccine Injury Compensation Program (VICP). The VICP—a “no-fault” alternative to traditional civil court lawsuits—was enacted after vaccine makers had been hit hard with high-profile lawsuits. Under the VICP, drug companies and negligent doctors are granted immunity against most lawsuits from injuries related to vaccines. The small percentage of damages that are awarded (only after years of litigation) are funded by *taxpayers*, and distributed by the federal government. (The compensation money comes from a 75-cent surcharge paid by consumers for each vaccine they receive.)

No matter how much money the federal government pays in damages to parents whose children have been hurt by vaccines, there's no liability to the drug companies, who don't have to pay anything. The US Court of Federal Claims in Washington, DC, handles contested vaccine injury and death cases in what has become known as “vaccine court.”

If vaccines are truly safe, drug companies don't need immunity. Why are they exempt from the law?

GAVI Formed to Protect the Vaccine Industry (1999)

GAVI is an acronym for the Global Alliance for Vaccination and Immunisation (GAVI). Originally funded by Microsoft billionaire Bill Gates (through the Bill and Melinda Gates Children's Vaccine Program), GAVI's partners also include the International Federation of Pharmaceutical Manufacturers Association, the Rockefeller Foundation, United Nations Children's Fund, the WHO (World Health Organization), and the World Bank. GAVI is also partly financed by countries that participate in its mass inoculation programs. In turn, GAVI gives generous monetary aid to vaccine manufacturers.

GAVI was formed, Lisa Reagan writes, in “A Dragon By The Tail: The Corrupt World of Global Vaccine Politics,” immediately after “a US Congressional Government Reform Committee initiated an investigation into the rampant conflicts of interest between federal vaccine policy makers and manufacturers.”²⁸⁸

Advisory Committee on Immunization Practices Meets to Protect the Vaccine Industry (1999)

The Advisory Committee on Immunization Practices (ACIP) is, according to the CDC website, “a group of medical and public health experts that develop recommendations on use of vaccines *in the civilian population of the United States*.” [emphasis added]²⁸⁹ Note that the website specifically states the vaccination of “civilians,” and not everyone, which would also include members of the government!

In October 1999, the ACIP stated that in view of the scientific literature showing that thimerosal was harmful, the long term goal was to try to remove it from vaccines as soon as possible. However, writes medical doctor Russell Blaylock, nothing was done.

**The first duties of
the physician is to
educate the masses
not to take medicine.**

—Sir William Osler, MD
“Father of Modern Medicine”
(1849–1919)

We have an important group here; the ACIP that essentially plays a role in vaccine policy that affects tens of millions of children every year. And, we have evidence from the Thimerosal meeting in 1999 that the potential for serious injury to the infant's brain is so serious that a recommendation for removal becomes policy. In addition,

they are all fully aware that tiny babies are receiving mercury doses that exceed even EPA safety limits, yet all they can say is that we must “try to remove thimerosal as soon as possible.” Do they not worry about the tens of millions of babies that will continue receiving thimerosal-containing vaccines until they can get around to stopping the use of thimerosal?

It should also be noted that it is a misnomer to say “removal of thimerosal” because they aren't removing anything. They just plan to stop adding it to *future* vaccines once they use up existing stocks, which entails millions of doses. And, incredibly, the government allows them to do it. Even more incredibly, the American Academy of Pediatrics and the American Academy of Family Practice similarly endorse this insane policy. In fact, they specifically state that children should continue to receive the thimerosal-containing vaccines until new thimerosal-free vaccine can be manufactured at the will of the manufacturers. . . . The most obvious solution was to use only single-dose vials, which requires no preservative. So, why don't they use them? Oh, they exclaim, it would add to the cost of the vaccine. Of course, we are only talking about a few dollars per vaccine at most . . .²⁹⁰

Nerve Damage from Thimerosal Suppressed (2000)

On June 7 and 8, 2000, over fifty scientists from the CDC, the FDA, and the vaccine industry met at the Simpsonwood Retreat Center in Norcross, Georgia, US. The official title of the meeting was “Scientific Review of Vaccine Safety Datalink Information,” and the vaccine representatives were from Smith Kline Beecham, Merck, Wyeth, North American Vaccine, and Aventis Pasteur. This secret meeting—which was neither announced in the Federal Register nor open to the public—was headed by Dr. Walter Orenstein, who at the time was director of the CDC’s National Immunization Program. A transcript of the meeting revealed that the topic of discussion was data showing a statistically significant correlation between mercury-containing vaccines and neurological disorders. The discovery, writes Reagan, “was made by CDC employee Thomas Verstraeten, MD, *using the CDC’s own data.*” [emphasis added]²⁹¹ This report was so secret, it had to be obtained through the Freedom of Information Act or FOIA (a law that allows people to more easily access information from the federal government).

After the meeting, Verstraeten did not respond to a US Congressional subpoena but instead left the CDC to work for a vaccine manufacturer in Belgium. However, Congress was able to question others who were at the meeting. Four years later, Dr. Russell Blaylock managed to obtain a copy of the original report and wrote in detail about it. His account reads, in part:

It all started when a friend of mine sent me a copy of a letter from Congressman David Weldon, MD, to the director of the CDC, Dr. Julie L. Gerberding, in which he alludes to a study by a Doctor Thomas Verstraeten, then representing the CDC, on the connection between infant exposure to thimerosal-containing vaccines and neurodevelopmental injury. In this shocking letter Congressman Weldon [refers] to Dr. Verstraeten’s study which looked at the data from the Vaccine Safety Datalink and found a significant correlation between thimerosal exposure via vaccines and several neurodevelopmental disorders including tics, speech and language delays, and possibly to ADD.

Congressman Weldon questions the CDC director as to why, following this meeting, Dr. Verstraeten published his results, almost four years later, in the journal *Pediatrics* to show just the opposite, that is, that there was no correlation to any neurodevelopmental problems related to thimerosal exposure in infants.

I contacted Congressman Weldon’s legislative assistant and he kindly sent me a complete copy of this report. Now, as usual in these cases, the government did not give up this report willingly, it required a Freedom of Information Act lawsuit to pry it loose. Having read the report twice and having carefully analyzed it; I can see why they did not want any outsiders to see it. It is a bombshell.²⁹²

Another person who has written extensively about the problems caused by thimerosal in vaccines and its cover-up is Robert F. Kennedy, Jr. Verstraeten, he wrote, performed:

the first large study of over 100,000 American kids whose vaccine and medical records were stored in CDC’s Vaccine Safety Datalink (VSD). Verstraeten provoked alarm with in the vaccine industry community when his data showed clear causative links between thimerosal and neurological damage, including autism. “The harm,” Verstraeten observed, “is done in the first month of life by thimerosal in vaccines.” He wrote in a December 17, 1999 e-mail to Robert Davis, a leading pharmaceutical industry consultant, that despite “running, rethinking, rerunning, and rethinking” the damaging effect of thimerosal persisted. He titled his 1999 e-mail, “It just won’t go away.”

When Thomas Saari, a spokesperson for American Academy of Pediatrics reviewed Verstraeten’s data, he panicked. “What if the lawyers get hold of this?” he wrote in an e-mail to his colleagues, “There’s not a scientist in the world that can refute these findings.”²⁹³

Only those who want to remain ignorant refute the vaccine-autism connection. In 1970, the autism rate in the US was 1 in 10,000. Today, it’s 1 in 68. Reagan states that “studies conducted or funded by the CDC that purportedly dispute any correlation between autism and vaccine injury have been of poor design, underpowered, and fatally flawed. The CDC’s rush to support and promote such research is reflective of a philosophical conflict in looking fairly at emerging theories and clinical data related to adverse reactions from vaccinations.”²⁹⁴ Despite abundant irrefutable data, the FDA continues to claim that thimerosal in vaccines is safe. If the mercury compound is removed, the FDA implies that it’s indulging consumer fears, rather than responding to real danger. More studies showing the link between thimerosal and autism are at whale.to/vaccine/Thimerosal_Immune_System_Abnormalities.pdf.

Vaccine Makers Granted More Immunity (2005)

On January 24, 2005, seven US senators introduced Senate Bill 3 (which was rapidly passed) that protected drug manufacturers from even more liability if their vaccines caused harm. “The bill,” writes Reagan, “is an unprecedented act giving comprehensive liability protections to vaccine manufacturers, restricting Freedom of Information Acts on drug/vaccine safety, and pre-empting states’ rights to ban mercury from children’s vaccines, all under the bill’s official title: ‘Protecting America in the War on Terror Act of 2005.’”²⁹⁵ That same year, the Global Alliance for Vaccines and Immunization accounted that it received \$750 million for its world vaccination campaign. Federal agencies shielded Big Pharma, but it was US taxpayer money that paid for the development of new vaccines.

The time required for the safety testing of vaccines is much less now than in the past. Vaccines are marketed quickly. If vaccines are safe, why do drug companies need immunity and why are they outside the law?

Polio from Vaccine in Nigeria (2007)

Polio, an inflammation of the spinal cord due to pathogens, toxins or nutritional deficiencies, can cause muscle atrophy and occasionally (but not always) paralysis. A polio scare in the 1940s and 1950s in the US led to the development of a vaccine. But in the last twenty years, the fear of polio has extended far beyond the North American continent.

In 2007, the *Canadian Press* documented a cause-and-effect relationship between the administration of vaccines in Nigeria and a subsequent rise in the vaccine-specific disease.

Nigeria has found 69 cases of children paralyzed by polio not caused by wild polio viruses, but rather weakened [“modified live”] viruses from polio vaccine that have circulated and regained their power to cause disease. . . . The vaccinated children shed viruses in their stools for weeks. Those viruses mutate. If they circulate long enough, the built-up mutations can restore the virulence stripped out in the vaccine production process, giving these viruses back the power to paralyze months and even years after their progenitors came out of a vaccine vial.²⁹⁶

Pro-vaccine officials insisted that the polio outbreak was due to an overall decrease in vaccinations, rather than the modified live viruses in the vaccines that had been given just before the outbreak.

Multi-Dose Vaccines Cause Disability, Death (2010)

In 2010, in association with GAVI, several countries participated in a program to inoculate their populations with multi-dose (five in one) vaccines. The countries included Pakistan, India, Sri Lanka, Bhutan, and Japan. A report made available to *The Express Tribune* stated that the program should be suspended until an investigation proved that the vaccines were safe for children, because 5,417 children had contracted the very diseases for which they had been inoculated. “The report stated that five deaths have been reported in Japan this year soon after the

vaccination was administered while 25 serious adverse reactions, including five deaths, were reported in Sri Lanka in 2008. Consequently, the vaccine was withdrawn. Bhutan also withdrew the vaccines after the deaths of children. The Association of Parents of Disabled Children from Bosnia and Herzegovina filed criminal charges after the GAVI-funded vaccines caused disabilities.”²⁹⁷

A Fraudulent Mumps Vaccine (2010)

On August 27, 2010, two former virologist employees of Merck filed a Complaint for Violations of the Federal False Claims Act in a US Court. The brief stated that for over a decade, the scientists had been pressured by their superiors and senior management at Merck to participate in a scheme to “defraud the United States with respect to the efficacy of Merck’s mumps vaccine” and take part in a “subsequent cover-up.” Merck had used “improper testing techniques and falsified test data to fabricate a vaccine efficacy rate of 95 percent or higher . . . [the efficacy rate that] the FDA insists for its licensing and approval of the vaccine.” Merck’s fraud included spiking the blood test with animal antibodies to artificially inflate the presence of immune activity. Moreover, the virus strain in the vaccine was different from what was actually infecting people in the real world. “The United States has over the last decade paid Merck hundreds of millions of dollars for a vaccine that does not provide adequate immunization,” the complaint read; and for the MMR2 vaccine (which contains the mumps formula), the US government paid even more: “between a half and three-quarters of a billion dollars.”²⁹⁸ Merck threatened employees who wanted to report the fraud to the FDA.

Star Brazilian football player Neymar was one person who had been inoculated with this vaccine and caught the mumps. Too ill to play, he missed two games—the prestigious Union of European Football Associations Super Cup and the Spanish Super Cup.

Deaths from Polio Vaccine in Pakistan (2010)

The worldwide effort to administer polio vaccines has continued. Here is an account from *The Express Tribune* of what occurred in Pakistan.

A government inquiry has found that polio vaccines for infants . . . are causing deaths and disabilities in regional countries including Pakistan. . . . The Prime Minister's Inspection Commission . . . has recommended that Prime Minister Yousaf Raza Gilani immediately suspend the administration of all types of vaccines funded by the GAVI.

The report . . . also suggested suspending the mass polio campaign, including the administration of pentavalent vaccines—a mixture of five vaccines to cure five diseases—until an inquiry finds these vaccines safe for children.²⁹⁹

Paralysis from Polio Vaccine in India (2011)

This time, the administration of the polio vaccine was done in India, under the auspices of the World Health Organization (WHO) in association with the Bill and Melinda Gates Foundation. According to statistics on paper, the inoculation program was a success. But the facts tell us something completely different. An article in a 2012 issue of *Indian Journal of Medical Ethics*, written by two doctors from the Department of Pediatrics at a hospital in India, reported:

While India has been polio-free for a year, there has been a huge increase in non-polio acute flaccid paralysis (NPAFP) [also simply called “acute flaccid paralysis,” or AFP]. In 2011, there were an extra 47,500 new cases of NPAFP. Clinically indistinguishable from polio paralysis but twice as deadly, the incidence of NPAFP was directly proportional to doses of oral polio received. Though this data was collected within the polio surveillance system [India's National Polio Surveillance Project], it was not investigated. . . . [Moreover, children with NPAFP] were at more than twice the risk of dying than those with wild polio infection.³⁰⁰

The authors, obviously and justifiably distressed, added that the polio vaccination program:

increased the incidence of other diseases and [has] broken the first rule of medicine—*primum non nocere*—first do no harm. . . . From India's perspective the exercise has been extremely costly, both in terms of human suffering and in

monetary terms. It is tempting to speculate what could have been achieved if the \$2.5 billion spent on attempting to eradicate polio, were spent on water and sanitation Ethicists will ask . . . why champions of the programme continued to exhort poor countries to spend scarce resources on a programme they should have known, in 2002, was never going to succeed.”³⁰¹

This was yet one more sad case where the cure was deadlier than the disease.

Vaccine Makers Granted Even More Immunity (2011)

In a 2011 landmark decision, the United States Supreme Court shielded Big Pharma from all civil liability for injuries and deaths caused by FDA licensed vaccines. Barbara Loe Fisher, author and co-founder of the National Vaccine Information Center, writes:

Meaningful congressional oversight on vaccine regulation and policymaking is non-existent today, in part because the pharmaceutical industry is the number one wealthiest and most powerful lobby on Capitol Hill [the seat of the US government]. . . . Parents, who file a claim today on behalf of a brain damaged vaccine injured child . . . know that the odds of obtaining financial assistance from the government are not much better than the odds of winning a lottery. Department of Health and Justice officials fight almost every award in the US Court of Claims so two out of three vaccine injury claims are denied.”³⁰²

Again, why are drug companies granted immunity if vaccines are truly safe? The federal government obviously doesn't care about protecting the people whose tax money supports it. Why?

Despite the tendency of doctors to call modern medicine an “inexact science,” it is more accurate to say there is practically no science in modern medicine at all. Almost everything doctors do is based on a conjecture, a guess, a clinical impression, a whim, a hope, a wish, an opinion or a belief. In short, everything they do is based on anything but solid scientific evidence. Thus, medicine is not a science at all, but a belief system. Beliefs are held by every religion, including the Religion of Modern Medicine.

(1926–1988)

The term “poliomyelitis” is a description of spinal pathology. The meaning of the word comes from Greek: *polios*=gray, and *meles*=marrow, *itis*=inflammation; meaning “inflammation of the gray matter of the spinal cord.” All poliomyelitis means is that the gray matter of the spinal cord is inflamed. This can occur anywhere from the brainstem to the end of the spinal cord, and it has always had many causes, the least of which is a virus that lives in intestines of healthy people.

The result of this inflammation, whether chemical or viral, leads to certain characteristic muscular symptoms that have been conditioned into the minds of several generations of people to appear as the classic atrophied limbs, iron lungs and other horrifying images.

By definition and by historical documentation, these infamous images of polio should by no means be blamed solely on a specific wild-type (naturally occurring) virus. Environmental toxins, other infections, and laboratory-derived vaccine viruses were all implicated in paralytic polio over the years. Yet wild virus, even though it is said to be asymptomatic in 95% of infected, and only causes paralysis in a small amount of infected, is the excuse for world-wide polio vaccination with live viruses that are known to cause their own outbreaks of polio in China, Nigeria and India. . . .

Naturally existing polio is thought to have been a normal bowel commensal [resident, without causing injury] for hundreds of years before paralytic polio emerged as an epidemic disease, beginning in white populations. For instance, an in-depth study of a remote Indian tribe in the Rio das Mortes in the State of Mato Grosso, Brazil demonstrated the presence of the virus with consistent and high levels of immunity—and no disease. . . . Native populations are known to have harbored polioviruses of all three strains with no poliomyelitis whatsoever. . . . Any thinking person would have to wonder what changed to make the natives and the non-natives become paralyzed from an otherwise completely innocent viral bowel commensal. . . .

[Circumstances] that are known by polio scientists and well documented in medical literature to be highly correlated with paralytic forms of polio include tonsillectomy, intramuscular injections of any sort, vaccines, DDT, arsenic, misdiagnosed syphilis, coxsackie virus, [and] other enteroviruses, just to name a few.

CDC Admits Polio Shot Contained Carcinogenic SV40 (2013)

The Simian vacuolating virus 40 (SV40) is a pathogen often found in cancerous tissue. It overrides the host’s genes that normally suppress the growth of tumors, so as a result tumors grow more readily. SV40 is generally found in monkeys and not humans. But in the early 1950s, after Dr. Jonas Salk grew a polio virus for his oral vaccine on the kidneys of rhesus monkeys, SV40 jumped to humans. Not surprisingly, the number of cancer cases increased.

I will do my best to explain the facts of this convoluted tale as simply as possible. Between about 1955 and 1963, approximately 90% of children and 60% of adults in the US were inoculated with polio vaccines contaminated with SV40. This numbered over 98 million people. Dr. Michele Carbone, an oncologist at Loyola University Chicago Medical Center in Illinois, US, isolated pieces of the SV40 virus in 33% of the osteosarcoma bone cancers studied, 40% of other types of bone cancers, and in 60% of mesotheliomas lung cancers. (Prior to 1950, mesothelioma was quite rare; but after the creation of contaminated vaccines, the incidences of this disease steadily rose.) Carbone’s research about the connection between vaccines and mesothelioma was so compelling, that the third part of an article called “The Virus and the Vaccine,” published in *The Atlantic Monthly* in February 2000, was devoted to the doctor’s research.³⁰³

In 2005, a paper was published in *Cancer Research*, titled “Some Oral Poliovirus Vaccines Were Contaminated with Infectious SV40 after 1961,” written by Carbone, Rochelle Cutrone (whose name appeared first on the article), and colleagues.³⁰⁴ The possibility of contamination was real, because even though a federal law had been passed in 1961 that prohibited new batches of polio vaccine from containing SV40, the law did not require the destruction of contaminated vaccines that had been manufactured before the law was passed. Therefore, pharmaceutical companies were still free to distribute all of the tainted materials until the supply was gone. Furthermore, new batches of vaccine produced afterward *were allowed to be created from the original infected seed lot*. This means that the SV40 virus would continue to be disseminated to anyone who received a polio vaccine.

Despite the lax supervision of vaccine manufacturers, the study did not find the levels of contamination that one might expect. The researchers wrote: “All the vaccines were SV40 free, except for vaccines from a major eastern European manufacturer that contained infectious SV40. We determined that the procedure used by this manufacturer to inactivate SV40 in oral poliovirus vaccine . . . did not completely inactivate SV40.”³⁰⁵

This potentially relieving conclusion might have ended the discussion. But other doctors questioned the quality control measures that the drug companies had implemented. They suspected that subsequent batches of polio vaccine *did*, in fact, contain SV40. (They evidently were aware of the initial problem that had existed before 1961, when the original oral polio vaccine was created; see Sidebar, “Even in 1966, Polio Vaccines Were Known To Be Carcinogenic.”) Their suspicions were apparently justified, because as it turns out, the testing methods used to determine the contamination of the vaccine batches were very sloppy. It’s not known if the vaccines that were tested were even for polio, what the amounts were, or which manufacturers were represented! The SV40 Cancer Foundation discusses this study in depth, and then describes a well done, subsequent study (also involving Dr. Carbone), which revealed much more contamination, and in more lots of vaccines.

The SV40 Cancer Foundation website states:

If a first year graduate student was to write up a study like this [the one conducted for “Some Oral Poliovirus Vaccines Were Contaminated with Infectious SV40 after 1961”] no doubt they would get an “F.” But, this is the quality of the work that a major governmental body uses when it comes to SV40 and vaccines. The result in this paper is that the spread of SV40 is blamed on a major eastern European vaccine manufacturer whose vaccine did not come into the U.S. or U.K., and other vaccine manufacturers such as those in the U.S. and U.K. are off the hook.

As bad as this first study is, the second one is good. After the NIBSC [National Institute for Biological Standards and Control] found SV40 in the vaccines from the major eastern European vaccine manufacturer they shipped it off to independent labs, including Dr. Carbone at Loyola University in Chicago. [This time, Carbone was able to perform proper tests.] There, Dr. Carbone’s group put the EEVM positive samples through a battery of tests including PCR, transfection, and direct infection of susceptible cell cultures. His analysis confirmed the presence of SV40 and even identified the strains. In discussing one of the strains, Dr. Carbone wrote, “The other strain that we detected, CPC-MEN, was originally isolated in 1984 from a human brain tumor in a German patient. The same virus was independently isolated from a brain tumor of a U.S. patient in 1995. Here, there is evidence that a specific type of SV40 from the polio vaccine was found in human brain tumors in Europe and the U.S.”

This is important information. The larger question, however, is why didn’t the NIBSC send all of its samples from “current or recent seed lots” of all three poliovirus serotypes from Belgium, Canada, France, Germany, Indonesia, Iran, Japan, Mexico, United Kingdom, United States, Vietnam, the former Yugoslavia and the World Health Organization to Carbone and other labs for independent analysis and confirmation?

Even in 1966, Polio Vaccines Were Known To Be Carcinogenic

Autism and Intestinal Problems

As parents have long reported, many children with autism experience severe gastrointestinal (GI) problems and the associated discomfort can worsen behavior. Researchers, in turn, have found a strong link between (GI) symptoms and autism severity. Some experts have even proposed that toxins produced by abnormal gut bacteria may trigger or worsen autism in some children.

Now scientists at Columbia and Harvard universities report that the GI activity of children with autism differs from that of other children in two key ways:

- 1) Their intestinal cells show abnormalities in how they break down and transport carbohydrates [necessary for the body's manufacture of serotonin, a key neurotransmitter that helps calm the brain], and
 - 2) Their intestines are home to abnormal amounts of certain digestive bacteria. (Bacteria play an important role in normal digestion. But abnormal levels of certain bacteria have been associated with digestive problems and intestinal inflammation.)
- The two findings are likely related, the researchers propose. Alterations in how intestinal cells break down carbohydrates can affect the amount and type of nutrients that these cells provide to intestinal bacteria. This, in turn, may alter the makeup of the intestine's normal community of digestive bacteria—with ill results.

"The findings are consistent with other research suggesting that autism may be a system-wide disorder, says study co-author Mady Hornig, M.D., director of translational Research at Columbia University's Center for Infection and Immunity. The study is available through the online scientific journal *PLOS-One*.

The findings may also explain why many parents of children with autism report that special diets and probiotics (nutritional supplements containing "good" bacteria) improve not only their children's digestion but also their behavior . . .

"GI problems are a common and distressing concern for many children and adolescents with ASD and their families," explains Autism Speaks Chief Science Officer Geraldine Dawson, Ph.D. "These conditions are not only a strain on the health of the children affected, GI problems can seriously interfere with their ability to participate in and benefit from activities of daily life, education and therapeutic activities."

. . . Government laboratories and labs tied to vaccine manufacturers or government funding report that they tested various polio vaccines for SV40 and for the major western manufacturers everything is okay. These governmental sponsored studies, however, never allow their results to be independently verified as required by the scientific method.³²⁰

So, even if vaccines were the most effective and safe drugs in the world, would you consent to being inoculated if there was a possibility of contamination—to the extent that you might develop cancer later?

This story has emerged in stages. The initial revelations did not receive the public notice that they deserved, but what's interesting is that at some point, this data actually appeared on the CDC website. It's difficult to determine exactly when the data appeared, because it was very quickly removed by the CDC and suppressed by Google. But before the CDC page vanished, its image was captured and posted on numerous other sites. The date of the earliest reposting that I could find is 2013.

CDC Exposed for Hiding Data Showing Link Between Autism and the MMR Vaccine (2014)

An alarming controversy involving the CDC—the suppression of yet more data on the harm caused by vaccines—exploded in the media in August 2014. But the origin was published data that the CDC had succeeded in discrediting, and then suppressing, sixteen years earlier. Here's how it happened.

In February 1998, the medical journal *Lancet* published an article written by British surgeon Andrew Jeremy Wakefield (who specialized in intestinal disorders) and twelve co-authors, called "Ileal-lymphoid-nodular hyperplasia, non-specific colitis, and pervasive developmental disorder in children."³²¹ The authors "investigated a consecutive series of children with chronic enterocolitis and regressive developmental disorder." Twelve boys (average age, 6 years) had initially been referred to a pediatric gastroenterology unit because they were suffering from diarrhea and abdominal pain, accompanied by "chronic enterocolitis and regressive developmental disorder." As the boys were evaluated—with, among other tests, "biochemical, haematological, and immunological profiles"—it became clear that ten of them had severe abnormalities. Ten displayed neurological disorders: autistic behavior (nine) and psychosis (one). Eleven of the boys suffered from chronic inflammation of the colon, which is common in autistic children. And two of the children appeared to have encephalitis. It was significant, said the authors, that the boys had "a history

of normal development followed by loss of acquired skills, including language, together with diarrhoea and abdominal pain.” Most important was the researchers’ conclusion:

Onset of behavioural symptoms was associated, by the parents, with measles, mumps, and rubella vaccination in eight of the 12 children, with measles infection in one child, and otitis media in another. All 12 children had intestinal abnormalities, ranging from lymphoid nodular hyperplasia to aphthoid ulceration. . . . We identified associated gastrointestinal disease and developmental regression in a group of previously normal children, which was generally associated in time with possible environmental triggers.³²²

Thus, this article with an unassuming title contained a bombshell: information that linked the combination measles, mumps and rubella formula—the MMR vaccine—to a high incidence of autism in young African-American boys. As might be expected, evidence that children regressed after receiving the vaccine wasn’t good for business, for either doctors or the vaccine industry. But rather than maintain an open, curious, questioning mindset and respond, “Really? We should look into this further,” the medical community reacted with indignation and hostility. In 2004, *Lancet* issued a retraction of the article by Wakefield et al. The *Lancet* website and many Internet medical databases, which ordinarily display the full text of an article, showed only the title with “retracted” in large red capital letters across it. (A few databases did include the abstract, but not the full text.) Wakefield was portrayed as not only unethical, but a criminal; several writers published articles faulting his research and conclusions. Wakefield was accused of receiving monies from people who profited from the information disclosed in his paper. His medical license was also revoked by the UK’s General Medical Council.

Throughout this vicious smear campaign clearly designed to damage his reputation, Dr. Wakefield consistently and resolutely defended his research and conclusions, saying that no fraud, hoax or profit motive was involved. He also stated that his original 1998 findings were “replicated in Canada, in the US, in Venezuela, in Italy . . . [but] they never get mentioned. All you ever hear is that no one else has ever been able to replicate the findings. I’m afraid that is false.”³²³

Vindication finally came in 2015. A press release was issued, titled “Ongoing Investigations by Dr. David Lewis Refute Fraud Findings in Dr. Andrew Wakefield Case,” with the subtitle, “Well-known Whistleblower Calls for

Heads, We’re Right— Tails, You’re Wrong

In 1976, children received 10 vaccines before attending school. Today they will receive more than 36 injections. The American Academy of Pediatrics and the Centers for Disease Control and Prevention assured parents that it was safe to not only give these vaccines, but that they could be given at one time with complete safety. Is this true? Or are we being lied to on a grand scale?

The medical establishment . . . [acts as though they are] the unique holders of medical wisdom—the mantra is “evidence-based medicine”—as if everything outside their anointing touch is bogus and suspect. . . .

I find it interesting that there exists an incredible double standard when it comes to our evidence versus theirs. The proponents of vaccination safety can just say they are safe, without any supporting evidence what-so-ever, and it is to be accepted without question. They can announce that mercury is not only safe, but that it seems to actually increase the IQ, and we are to accept it. They can proclaim thimerosal safe to use in vaccines without their having ever been a single study on its safety in more than 60 years of use, and we are to accept it.

Yet, let me, or anyone else, suggest that excessive vaccination can increase the risk of not only autism, but also schizophrenia and neurodegenerative diseases, and they will scream like banshees—where is the evidence? Where is the evidence? When we produce study after study, they always proclaim them to be insufficient evidence or unacceptable studies. More often than not, they just completely ignore the evidence. This is despite the fact that we produce dozens or even hundreds of studies that not only demonstrate the link clinically and scientifically, but also clearly show the mechanism by which the damage is being done—even on a molecular level. These include cell culture studies, mixed cell cultures, organotypic tissue studies, *in vivo* animal studies using multiple species, and even human studies. To the defenders of vaccine safety our evidence is never sufficient and, if we face reality, never will be.

We see how questions of medical importance that are nitpicked to death on points of [presumed] scientific purity can cost a lot of lives—millions of lives.

Autism Spectrum Disorders”

Withdrawal of *British Medical Journal* Article Alleging Fraud.” The whistleblower was research microbiologist David Lewis—a member of the National Whistleblowers Center Board of Directors and Director of its Research Misconduct Project, a former senior-level research microbiologist for the US Environmental Protection Agency, and a distinguished author in his own right with publication credits in many prestigious journals and magazines. The press release quoted Lewis as follows:

There was no fraud committed by Dr. Wakefield. . . . The grading sheets and other evidence in Wakefield’s files clearly show that it is unreasonable to conclude, based on a comparison of the histological records, that Andrew Wakefield ‘faked’ a link between the MMR vaccine and autism . . . Now that these records have seen the light of day, it is time for others to stop using them for this purpose as well. False allegations of research misconduct can destroy the careers of even the most accomplished and reputable scientists overnight. It may take years for them to prove their innocence; and even then the damages are often irreparable. In cases where mistakes are made, every effort should be taken to fully restore the reputations and careers of scientists who are falsely accused of research misconduct.³²⁴

This, then, is a brief history of the earliest known claim that the MMR vaccine can cause autism. What about the more recent controversy involving the CDC?

On August 26, 2014, Natural News website owner Mike Adams acquired a copy of an email, from an undisclosed source, that CDC employee Dr. William Thompson had sent to nine (named) recipients. The email focused on a Department of Justice investigation of the CDC, which in response to the earlier Wakefield studies had done its own research on the MMR vaccine and autism in 2002. The CDC confirmed Wakefield’s findings—that the MMR vaccine, when given to African-American boys under age 3, did indeed cause a 340% increased risk of autism. (The study was not intended to examine the autism risk beyond age 3.) In Thompson’s email, he mentioned that CDC personnel were trying to decide which documents to make available to the Department of Justice and which documents to withhold.

Less than 24 hours after Mike Adams published the formerly secret email, Dr. Thompson—now forced into the role of CDC whistleblower—had a statement posted on the website of the law firm that represented him. It immediately began with a blatant admission of scientific fraud at the CDC:

My name is William Thompson. I am a Senior Scientist with the Centers for Disease Control and Prevention, where I have worked since 1998.

I regret that my coauthors and I omitted statistically significant information in our 2004 article published in the journal *Pediatrics*. The omitted data suggested that African American males who received the MMR vaccine before age 36 months were at increased risk for autism.

. . . There have always been recognized risks for vaccination and I believe it is the responsibility of the CDC to properly convey the risks associated with receipt of those vaccines.³²⁵

It was impossible to misinterpret Thompson’s statement. He conceded that vaccines can be risky. He stated that the CDC had a moral obligation to publicly reveal these risks. And he said that it failed to reveal them.

After the story was made public, high ranking CDC officials refused to cooperate during a formal investigation by the US Congress. CDC personnel, including Dr. Coleen Boyle, outright lied under oath, stating there were no risks from the MMR vaccine. The head of the CDC from 2002 to 2009, Dr. Julie Gerberding, was also actively involved in the cover-up and tried to have Thompson punished for being a whistleblower. (After leaving the CDC, Gerberding became the new president of the Merck vaccine division.) However, Dr. Thompson told the truth. He admitted that he and the other co-authors “scheduled a meeting to destroy documents related to the study . . . [We] reviewed and went through all the hardcopy documents that we had thought we should discard, and put them into a huge garbage can.”³²⁶ Fortunately, Thompson kept copies of all the discarded materials, because he knew that concealing them was illegal and figured that someone might need to see them later.

Some prominent members of the African-American community, understandably livid, accused the CDC of conducting genocide against black men, and compared the administration of the vaccine to the Tuskegee experiment (see Sidebar, “The CDC’s Tuskegee Experiment”).

It’s significant that mainstream media did not cover this event—until compelling evidence from non-mainstream sources was disseminated so fervently that it could no longer be ignored. Mike Adams commented:

The release of those emails [by Natural News] may have been pivotal in Dr. Thompson’s choice to go public with his own statement. The vaccine establishment, which immediately and predictably accused Natural News of fabricating the two emails, is now backpedaling as rapidly as possible with the full knowledge that Dr. Thompson’s

public statement affirms and supports the authenticity of those emails.

The alternative media alone broke this story, pre-empting the *New York Times*, *Washington Post* and every Pulitzer-prize-winning journalist in the world. The tables have now turned. It is solely the alternative media which is now breaking most of the really important investigative stories of our time. . . . this also reveals that the entire world owes a massive and immediate apology to Dr. Andrew Wakefield whose career and reputation have been destroyed by the very people who conspired to commit scientific fraud at the CDC. We must all now call upon the media to run headlines like, “Dr. Wakefield Vindicated: MMR Vaccine Fraud Confirmed.”³²⁷

Since that fiasco, many “alternative” media sources interviewed Wakefield. He has written two books, *Callous Disregard* and *Waging War on the Autistic Child*. A few courageous medical journals outside the US have published his articles. Some of his work—including detailed rebuttal to the slanderous myths against him and his research, plus analyses of his data by other writers—are at wesupportandwakefield.com/scientific.asp.

Measles, the Ultimate Disneyland Fairy Tale (2015)

Measles, caused by a virus, infects almost all children at some point in their young lives. Symptoms include fever, runny nose, coughing, sneezing, fatigue, and the condition’s best known feature, a red skin rash. Although highly contagious, measles is not lethal. The child is fed liquids, kept warm in bed, and the disease runs its course. In this situation (normal circumstances), the child’s immune cells fight the virus and tag it—in other words, “remember” its presence and unique antigen pattern—so that in the future, there will be no more infections, and the child will not be able to infect anyone else.

It’s true that during the 1800s, measles was a noted cause of death. Roman Bystryanyk writes:

In Glasgow, England, from 1807–1812, measles accounted for 11% of all deaths. In the years from 1867–1872, 49% of children in a Paris orphanage who developed measles died. . . . [However, by 1963] the death rate from measles in the United States had already dropped by approximately 98%. . . . Deaths from asthma were 56 times greater, accidents 935 times greater, motor vehicle accidents 323 times greater, other accidents 612 times greater, and heart disease 9,560 times greater.

The CDC’s Tuskegee Experiment

Related to the CDC’s cover-up of the link between the MMR vaccine and autism in young black boys, is another crime that began over eight decades ago. Some call it the Tuskegee “clinical trials” or Tuskegee “study,” but in truth it was senseless, slow torture.

The main perpetrator was the US Public Health Service, which in 1946 founded the Communicable Disease Center that eventually morphed into the CDC. However, it had the full cooperation of an all-black college, the Tuskegee Institute in Alabama. The college agreed to support the “study” if it was given full credit and black professionals were involved. The stated purpose of this “study” was to record the natural progression of syphilis, which was rampant at the time, so that treatment programs for black people could be developed and implemented.

The subjects of this cruel experiment were male African-American adults. Between 1932 and 1972, 600 impoverished sharecroppers—399 who had syphilis, and 201 who did not—were recruited from Macon County, Alabama. The researchers told the men that they were being treated for “bad blood.” The men were also told that during their complimentary physical exams, they would receive medical treatment to cure their condition. Instead, they were given free meals, regular rubdowns with poisonous mercury salve (!), and burial insurance.

The first articles concerning this “study,” in 1934, stated the health dangers of untreated syphilis. In 1936, local physicians were asked to help with the “study” but not to treat the men, whose decline they followed until the men died. In 1940, the military gave orders not to give the men medical care. In 1947, the Public Health Service established centers to dispense penicillin for syphilis (the best known treatment at the time), but this was withheld from the Tuskegee experimentees.

Even though concerns were raised in 1968 about the ethics of the experiment, in 1969 the CDC—with the support of the local AMA—reaffirmed the need to continue the “study.” After news articles condemning this experiment were published in 1972, it ended. In 1973, the US Congress held hearings and a class action lawsuit was filed on behalf of the subjects, who began receiving compensation a year later. Wives, widows, and offspring were given benefits in 1975. In 1997, US President Clinton issued a public apology. In 2004, the CDC gave ten million dollars (of taxpayer money) to the Tuskegee University National Center for Bioethics in Research and Health Care so it could conduct “research” there.

The timeline of events is clearly posted on the CDC website, cdc.gov/tuskegee/timeline.htm.

British Medical Journal Criticizes CDC's Bias

The CDC's image as an independent watchdog over the public health has given it enormous prestige, and its recommendations are occasionally enforced by law. Despite the agency's disclaimer ["CDC does not accept commercial support"], the CDC does receive millions of dollars in industry gifts and funding, both directly and indirectly, and several recent CDC actions and recommendations have raised questions about the science it cites, the clinical guidelines it promotes, and the money it is taking. . . . Industry funding of the CDC has taken many doctors, even some who worked for CDC, by surprise. . . .

Funding of CDC took a turn in 1983, when the CDC was authorised to accept external "gifts" from industry and other private parties. In 1992, Congress passed legislation to encourage relationships between industry and the CDC by creating the non-profit CDC Foundation, which began operations in 1995. The CDC Foundation raised \$12 [million] . . . from corporations.

. . . In December 2009 . . . the [Office of the] Inspector General evaluated conflicts of interest of advisors and concluded, "CDC has a systemic lack of oversight of the ethics program": 97% of disclosure forms filed by advisors were incomplete, and 13% of advisors participated in meetings without filing any disclosure at all. . . . Following criticism of the CDC and its foundation for accepting a directed donation from Roche for the agency's Take 3 flu campaign . . . the CDC posted an article on its website entitled, "Why CDC Recommends Influenza Antiviral Drugs." The agency cited multiple observational and industry funded studies . . . which it described as . . . "independent" . . .

In 2012, Genentech earmarked \$600,000 in donations to the CDC Foundation . . . Genentech and its parent company, Roche, manufacture test kits and treatments for hepatitis C. . . . The CDC has also been criticised for its role in a series of studies into an epidemic of chronic kidney disease among men working in the sugar fields of central America. The sugar industry is paying \$1.7 [million] to fund the studies. . . . Researchers think that the epidemic, which has killed over 20,000 mostly young men, is most likely to be caused by "two interdependent factors: the misuse of agrochemicals . . . [neurotoxic pesticides] . . . and the working conditions of the labor force."

Jerome R. Hoffman, a methodologist and emeritus professor of medicine at UCLA said, "Most of us were shocked to learn the CDC takes funding from industry. . . . it was our government that made this very bad arrangement, so the way to fix it is not to ask the CDC to 'pretty please be more ethical, and avoid conflicts of interest' . . . we have to get the government to reject this devil's bargain, by changing the rules so this can no longer happen."

—Jeanne Lenzer

"Centers for Disease Control and Prevention: protecting the private good?" *British Medical Journal*, May 15, 2015

In England the measles vaccine was introduced in 1968. By this point measles deaths were extremely rare. The actual death rate from measles in England had fallen by an almost full 100%. . . . After natural measles infection during childhood, reoccurrence of measles was rare.³²⁸

So, about the time that measles was regarded as an annoying and inconvenient—but relatively harmless—rite of childhood passage, Big Pharma began publicizing measles as something to be feared, worthy of a vaccine. Thus in 1963, a measles vaccine was introduced. This vaccine contained a weakened, live measles virus, which caused, in about half the children who received it, a much higher fever than they would have had if they'd simply contracted the disease normally. Doctors even had a name for this new disease caused by the measles vaccine: *atypical measles*. The symptoms, Bystranyk summarizes, included "a modified measles rash in 48 per cent of the children who received it and fever as high as 106 degrees [compared to 103 degrees, in a case of normal measles] in 83 per cent of them."³²⁹ Atypical measles was reported even 16 years after children received the weakened live measles vaccine.

Measles was not in the news very much until the media began extensively covering what it called a measles "epidemic." On January 7, 2015, an unnamed spokesperson from the Disneyland theme park in Anaheim, California, issued a warning to the public that there were at least seven confirmed cases of measles amongst the forty to fifty thousand people who visit Disneyland daily. The first infected person, whom the CDC believed to be a foreign visitor, had probably been at Disneyland in late December of the previous year. Again, keep in mind that this illness is from an admittedly irritating, but relatively benign, virus.

The dictionary, when referring to a disease caused by a pathogen, defines *epidemic* as "affecting or tending to affect a disproportionately large number of individuals within a population, community or region at the same time."³³⁰ (*Disproportionately* means "having or showing a difference that is not fair, reasonable, or expected: too large or too small in relation to something."³³¹) Yet another guideline for what qualifies as an "epidemic" is that the number of *deaths* (not illnesses) from a particular pathogen must exceed 7.7%;³³² although according to some sources, 7.7% of the population can simply become ill and not die. The CDC's official definition of *epidemic* is, "The occurrence of more cases of disease than expected in a given area or among a specific group of people over a particular period of time."³³³ This meaning is conveniently vague. It allows the CDC to change its rules about how many must become ill in order for a given disease to be labeled an "epidemic."

As we wade through this bewildering array of often imprecise definitions, the question arises: just how real *was* this measles epidemic?

Here are the numbers, as reported by the CDC. From January 1 to October 16, 2015, 189 people from twenty-four states and Washington, DC, were reported to have contracted measles. Of those, 131 people were from California, a huge state with a population of 38,802,500 (close to 39 million people), according to the 2014 census. For our calculations, even if we generously include those additional folks from out-of-state in our total, 189 who contracted measles out of 38,802,500 people in the entire state of California is, in percentages, 0.000487%. This hardly qualifies as an epidemic. Now let's look at the historic Bubonic Plague (also known as "Black Death"). Brought to Europe by infected rats on ships, it spread from about 1347 to 1353, killing the highest number of people around 1351. The Bubonic Plague eliminated 60% of the population of Florence, Italy, in just a few months. Now *that's* an epidemic! (About half of Europeans were dead in a few years, turning the epidemic into a *pandemic*.)

When people hear the word "epidemic" without stopping to think about what the numbers actually are, how serious the illness is, or even if there are any deaths, they allow fear to blind them. The fact is, measles is not life-threatening. The diagnosis may even be incorrect: "Measles is wrongly diagnosed in 97 per cent of cases, according to new data from the Public Health Laboratory Service . . ." ³³⁴ And a vaccine does not guarantee immunity in the person who's inoculated: true epidemics still occur in highly vaccinated populations, as illustrated by one of many titles, "Outbreak of Measles Among Persons With Prior Evidence of Immunity, New York City, 2011," which appeared in a 2014 edition of *Clinical Infectious Diseases: Oxford Journals*. ³³⁵ Notably, from 2004 to 2015—according to the CDC itself and the VAERS database—there were no deaths from measles, but there *were* 108 deaths from the measles *vaccine*. ³³⁶

Catering to the Disneyland media circus, Public Broadcasting Service lied, stating that one hundred people had died. The truth, however, was reported in an August 2015 *Los Angeles Daily News* column. More than 50% of measles sufferers during this "epidemic" had already been vaccinated—against measles.

Both vaccinated and unvaccinated individuals are at risk of contracting measles due to several reasons. Vaccine immunity wears off and live-virus vaccines, such as the MMR vaccine, sheds. If vaccine immunity wears off, and you can catch the disease from those shedding the virus after being recently vaccinated, then how does SB 277

actually protect anyone? . . . According to the CDC, there are a number of other states that have much lower vaccination rates and much higher opt-out rates than California. Yet, none of them has had any serious outbreaks. . . .

[SB 277] is about an out-of-control government bent on controlling your choices. . . . It wasn't "responsible Californians" who voted to deny parents' rights to make informed decisions about their child's health; it was 24 California senators who used the Disneyland measles outbreak as an excuse to increase government control over your children. . . . The question isn't whether to vaccinate or not to vaccinate. The question is whether parents should have the right to make an informed medical decision for their child's health. . . . [Anyone] endorsing SB 277 . . . is saying that the government should make that choice for you. . . . The massive, global pharmaceutical conglomerates that have a highly profitable monopoly on vaccines have absolutely no liability, so there is no incentive for them to improve the safety of their product. . . . SB 277 will not make anyone safer; it will only make people feel safer. ³³⁷

People with adequate stores of Vitamin A suffer the least from measles. Bystranyk writes that Vitamin A:

stops the measles virus from rapidly multiplying inside cells by up-regulating the innate immune system in uninfected cells which helps to prevent the virus from infecting new cells. It is well known today that a low vitamin A level correlates with increased morbidity and mortality . . . [and is also] a well-proven intervention for . . . concomitant infections, and hospital stay.

When the body fights any infection, but especially measles, vitamin A stores become depleted by various mechanisms. Measles infections and high-titer measles vaccines both impair cell-mediated immunity, in part because of vitamin A depletion. . . .

As early as 1932, scientists found that mortality dropped by 58 percent when children hospitalized with measles were given cod liver oil, which contains vitamins A and D and omega-3 fatty acids. Later studies in the 1990s showed amazing results of vitamin A reducing deaths by 60 to 90 percent. . . . By 2010 it was well accepted that supplementing with vitamin A during acute measles illness led to significant drops in both adverse outcomes and death. ³³⁸

Adequate Vitamin C is also key. As far back as the 1940s, researchers knew that high doses of C were effective against measles. From *Southern Medicine & Surgery*:

During an epidemic [of measles] vitamin C was used prophylactically and all those who received as much as 1000 mg. every six hours, by vein or muscle, were protected from the virus. . . . It was further found that 1000 mg. by mouth, four to six times each day, would modify the attack; with the appearance of Koplik's spots and fever, if the administration was increased to 12 doses each 24 hours, all signs and symptoms would disappear in 48 hours.³³⁹

Do we really need another vaccine? Or do we need quality nourishment that allows our immune cells to do their jobs?

The US Government - CDC Marriage

Private industry and government health offices such as the CDC or FDA should never be so cozy. It creates an environment of collusion between Big Government and Big Pharma. . . . the CDC already functions as the marketing division of the pharmaceutical industry.

Forced Vaccination in California, No Exemptions (2015)

After the Disneyland measles episode, a new law was passed. Despite the fact that very few people became ill, within weeks of this heavily publicized "epidemic" public health officials joined drug company executives and medical organization lobbyists, demanding mass vaccinations in California. They also urged the elimination of exemptions based on personal conscience, religious beliefs and most medical reasons. In response, on June 30, 2015, California governor Jerry Brown signed Senate Bill 277 (SB 277) for the mandatory vaccination of all schoolchildren. No exemptions based on personal belief or religious objections were allowed. Unvaccinated youngsters weren't permitted to attend public or private school, and toddlers were denied daycare unless they were inoculated.

To obtain a medical exemption for a child, parents had to apply to the Department of Public Health, and rely on the generosity of the state to opt out of vaccines. Governor Brown's official statement—which admitted that although vaccines can be risky, they're necessary to protect the community—was the complete opposite of a written announcement he'd issued three years earlier, in which he supported exemptions based on personal and religious beliefs.

SB 277 was passed unusually quickly, despite the thousands of people who publicly rallied to oppose the bill. Opponents knew that parents wouldn't be able to receive compensation if their children became ill or immune-

compromised from forced vaccinations, because legislation had already been passed that protects manufacturers from liability if someone is injured by a vaccine.

California Senator (and doctor) Richard Pan was the main public figure behind the state's mandatory vaccination law. In addition to his government duties, Pan was managing the pediatric training program at the University of California in Davis. The university conducts research and development of vaccines, gets paid to test vaccines, and receives additional funds to administer them. Not surprisingly, Big Pharma was a major contributor to Pan's campaign for senator.

Parents who were aware of the damage that vaccines cause were understandably upset. Some moved out of the state. Many of them withdrew their children from public school and began homeschooling. That August in *The Guardian*, "California home

school interest surges as parents look to sidestep vaccine law" described the new wave of homeschooling.

California has one of the largest populations of home-schooled children, with about 177,000 in some form of homeschooling, according to estimates by home-schooling expert Anne Zeise, who runs the website a2zhomeschooling.com. . . .

Diane Flynn Keith, who runs home-school information seminars in the San Francisco bay area, said her three-hour sessions have been filling to capacity since the law passed. Her most recent seminar earlier in August drew a sold-out crowd of 40, when normally she would expect about 25.

"At least 10 of the people there asked me specifically about vaccinations," she said. That demand has led her to add more events in the coming months. . . . Keith cautions parents that home schooling "is not easy" and those seeking a way out of vaccinations represent a "whole new group that are sort of being forced into it."³⁴⁰

Parents are challenging the law. They hope to achieve a similar outcome to that achieved in the state of Oregon, when a similar bill was defeated. Jennifer Margulis, PhD, had remarked to Oregon's Senate Committee on Health Care: "For me this is not a debate about the merits of vaccines, the harm vaccines may cause in a subset of vulnerable children, or whether or not the current CDC schedule is really in the best interests of our children's health. It is a debate about freedom and parental choice."³⁴¹

The political implications of this situation are extremely troubling. The law essentially allows the state to practice medicine without a license. It dictates how parents must raise their children—often under threat of having the child removed from the home. And the law denies people the freedom of choice in their health care. If mandatory inoculations occur in California, what's to prevent them from being implemented in other states? And with all adults, no matter how old or ill they are?

Not content to merely *push* vaccines, later in 2018, Senator Pan authored the “Online False Information Act.” His new bill required anyone who posts news on the Internet, *including information about vaccines*, to first verify all data with state-sanctioned “fact checkers.” Information disputed by Pan and his agents would have to be labeled “fake.”

Unavoidably unsafe products. There are some products which, in the present state of human knowledge, are quite incapable of being made safe for their intended and ordinary use. These are especially common in the field of drugs. An outstanding example is the vaccine for the Pasteur treatment of rabies, which not uncommonly leads to very serious and damaging consequences when it is injected. . . . The same is true of many other drugs, vaccines, and the like . . . It is also true in particular of many new or experimental drugs.

Worthless and Harmful Flu Shots Promoted (Ongoing)

Influenza (or simply “the flu”) is similar to a severe cold that affects the respiratory and gastrointestinal tracts. Symptoms usually include fever, chills, sore throat, head and muscle aches, sometimes coughing, and perhaps abdominal cramping and diarrhea. The flu is caused by any number of viruses, each with a slightly different protein coating. This makes it impossible for virologists to classify or identify all of them.

Another reason flu viruses can't easily be identified is their tendency for *antigenic drift*—a small genetic shift that occurs each time a flu virus replicates. These viruses are constantly replicating; so by the next season, they have mutated entirely. It takes an entire season for researchers to produce a vaccine. Thus, any inoculation you receive is always from last year. Even with the (standard) three strains of virus in one shot, vaccine manufacturers must *guess* which strain will cause the next wave of influenza. So there's no guarantee that what you're being given matches the virus that's currently causing the flu. This is why flu vaccines are ineffective. In addition, as a 2017 journal article reminds us, “influenza virus often mutates to adapt to being grown in chicken eggs, which can influence antigenicity and hence vaccine effectiveness.”³⁴² (This also helps further explain the growing allergy to eggs.)

No wonder receiving a flu vaccine is like a crap shoot! Nevertheless, this doesn't stop the drug industry (or the

CDC) from promoting whatever flu vaccine they have stockpiled. Each year in the US, signs in doctors' offices, drug stores, and supermarkets urge consumers to get their flu shots. Each year, hundreds of thousands line up to receive them. And each year, thousands of unfortunate folks experience negative reactions to these shots. The reactions range from temporary flu-like symptoms such

as runny nose, sore throat, swollen red “hot spots” on the skin and aching muscles and joints, to more severe conditions such as muscle weakness and pneumonia. Even more serious (that is, permanent) conditions include incontinence, muscle damage, the inability to walk, paralysis, autoimmune neurological disorders (such as the paralyzing Guillain-Barré syndrome), and cancer.

Studies have shown that not only does the flu vaccine cause quite a bit of damage,

but that it does not protect against influenza. In fact, it may introduce other pathogens, leading to illness that did not exist prior to the inoculation. The body may be weakened to such an extent that it has no resistance to subsequent pathogens. Here are just a few examples:

- ◆ “Influenza Vaccine Effectiveness in the Community and the Household” reported the results of an assessment of the effectiveness of the flu vaccine during the 2010–2011 flu season. There was no substantial difference between subjects who received the vaccine and those who didn't: both groups (adjusted for age and health) were similarly at risk to become ill from the flu. What surprised the researchers even more was that receiving the flu vaccine two years in a row actually *lowered* immunity to the current season's strain of influenza.³⁴³
- ◆ “Association between the 2008–09 Seasonal Influenza Vaccine and Pandemic H1N1 Illness during Spring–Summer 2009: Four Observational Studies from Canada” questioned whether repeated annual flu vaccinations are effective. It concluded that people who receive seasonal trivalent (three-strain) flu vaccines have a much greater risk of subsequently contracting the H1N1 swine flu. For instance, recipients of flu shots in the 2008–2009 season were between 1.4 and 2.5 times more likely to become infected with the H1N1 swine flu during spring and summer of 2009.³⁴⁴

- ◆ “Clinical and Epidemiologic Characteristics of an Outbreak of Novel H1N1 (Swine Origin) Influenza A Virus Among United States Military Beneficiaries” conducted an analysis similar to the above, except it was a military population. The authors found that 66% of people infected with the H1N1 swine flu had received flu shots sometime in the previous 12 months. (Naturally, the CDC disagreed.)³⁴⁵
- ◆ Great Britain has heavily inflated the number of flu deaths. The 2010 article, “UK Fakes Flu Death Numbers,” reported that the UK Department of Health claimed that 12,000 people die annually, but this is 360 times higher than the actual number of deaths from the flu. “Fictitiously high death rates from flu continue to be invoked, resulting in scaremongering despite scientific evidence [that] the vaccines are ineffective for at risk groups. In 2007 it was claimed that 25,000 people died from flu annually—720 times the 2010 figure.” Where did these figures come from? After leaving his post as Chief Medical Officer, Sir Liam Donaldson posted on the *British Medical Journal* website that the flu death figures were fabricated. He wrote that the annual mortality rates, according to the Office for National Statistics, were all based on death certificate information. “The number of deaths for England and Wales with an underlying cause of influenza . . . for the four recent calendar years are: 39 (2008), 31 (2007), 17 (2006), and 44 (2005).”³⁴⁶ How could these statistics be so inflated? Because, he wrote, the computations included all certificates that even *mentioned* influenza. The coronor routinely swabbed the mouth (which harbors all kinds of bacteria) to test for pathogens. If the deceased tested positive for influenza, even if they didn’t die from it, this was counted as a flu death.
- ◆ Immunogeneticist Hugh Fudenberg found that individuals he studied between 1970 and 1980 who received five consecutive flu shots had a ten times greater chance of developing Alzheimer’s than those who had received one, two, or no shots. This, Dr. Fudenberg noted, was due to the mercury and aluminum that every flu vaccine contains. The gradual buildup of mercury in the brain helps produce *amyloid plaques*—toxic sticky proteins that accumulate outside of nerve cells. This is the same plaque that causes cognitive dysfunction, and is one of the criteria used to diagnose Alzheimer’s.

Files of the inserts that accompany vaccines—which doctors rarely allow non-doctors to read—can be downloaded at: www.vactruth.com

- ◆ Fluzone® is a popular flu vaccine sold by doctors and chain drug stores. During the winter, the CVS chain store offers customers a 20% shopping discount if they receive a shot. The 22-page warning for Fluzone® advises that if Guillain-Barré syndrome (a life-threatening, autoimmune neurological paralysis) has occurred within six weeks *of a previous flu shot*, to be cautious about administering another shot. Common reactions include headache, muscle pain, skin rash and severe fatigue, and possibly encephalomyelitis (tingling and burning in the extremities, sleep dysfunction, muscle weakness and vision abnormalities), Bell’s palsy (facial paralysis), and blood, lymph and respiratory disorders. The literature states that although 23 people died after being vaccinated, none of the deaths were caused by the vaccine because all of the flu shot recipients were elderly. We are also advised that the vaccine might not protect everyone who receives it, and it might not be safe or effective for pregnant women.

Dr. David Brownstein remarks:

On January 3, 2014 I received [a medical report in] an email titled, “High Dose Flu Vaccine: The Evidence Is In.” This interested me as I have done extensive research on the flu vaccine and know that it is ineffective at preventing the flu . . . Describing the results of the study, the doctor said, “. . . The high-dose shot was more effective in seniors. It was 24% better at preventing the flu than the standard flu shot.” . . . My first thought was, “You gotta be kidding me!” The 24% improvement with the high dose vaccine was accurate—1.43/1.89 equals a 24% improvement. However, as I teach other doctors and medical students, this is the *relative* risk difference. This number is not to be used when considering whether a particular therapy would help a patient. The more accurate number is the *absolute* risk reduction. The absolute risk reduction between the vaccines was 0.46% (1.89%-1.43%). The headlines should read, “New Flu Vaccine is 0.46% More Effective.” Going one step further, *it takes 217 elderly people to receive the high dose flu vaccine to prevent one case of the flu. . . . 216 out of 217 elderly people received the flu vaccine for naught—it did not help them prevent the flu. . . .* This new flu vaccine is worthless and too expensive—it is double the price of the regular flu shot, which is also worthless. [emphasis added]³⁴⁷

Who Refuses Vaccines?

The mainstream press claims that people who decline, avoid, or oppose vaccines are at best, highly inconsiderate of the rest of us (the obedient and healthy vaccinated), and at worst, fanatics or sociopaths. In fact, a May 8, 2017 editorial in the *Boston Herald* insisted that those spreading “lies” about vaccines be hanged! (The newspaper has since removed the offending editorial from its website.) Despite what this negative press would like you to believe, vaccine opponents are not fringe members of the population—unless you define “fringe” as people who think for themselves, research the pros and cons of vaccination, and utilize common sense instead of blindly accepting vague assurances from government agencies. Similarly, parents who choose not to vaccinate their children are not neglectful or uncaring. On the contrary, they tend to be better educated, and have more money, than their pro-vaccine counterparts. They seek, read, and evaluate all the data they can find. Sometimes parents learn the truth the hard way, after inoculation—when the child either becomes autistic, suffers other neurological damage, contracts the pathogen in the vaccine, or dies.

Even medical industry personnel are rejecting vaccines. No longer able to deny the poor success rates and the risks, they decide not to be jabbed, and tell others not to accept shots either. Below is a very small sample.

- ◆ 2009: *General Practitioners (GPs) and Nurses in the UK and Canada*. A *GP Magazine* website survey “found that up to 60% of GPs may decline vaccination. Although the numbers who responded were small—216 GPs—they are in line with a much bigger survey of nurses published a week ago by *Nursing Times*, which found that a third of 1,500 nurses would refuse vaccination. . . . A Canadian study published today in the journal *Emerging Health Threats* suggests the public, too, will have reservations that must be overcome . . . The study . . . pointed to the need to win over people who believe that alternative therapies and a good diet are a better option than vaccines. But the biggest problem in persuading people and healthcare professionals to have the jab may be the relative shortage of evidence from trials about its safety and efficacy.”³⁴⁸
- ◆ 2009: *Another Honest British GP*. Physician Liz Miller bluntly stated that “she would not recommend the vaccine to her patients because of safety concerns: ‘I do not intend to be vaccinated, nor will I recommend it to patients. It is untested and unnecessary. It’s time doctors started thinking for themselves instead of mindlessly obeying the Department of Health because they are terrified of missing out on free money.’”³⁴⁹

Negative Reactions to Vaccines— Sometimes Acquiring the Disease Itself

- ◆ According to US government statistics, children under age 14 are three times more likely to suffer adverse effects (including death) following the hepatitis B vaccine than to catch the disease itself.
- ◆ The Centers for Disease Control admits that the reported number of adverse effects of vaccines is probably only 10% of actual adverse effects.
- ◆ The CDC’s own guidelines warn not to vaccinate children if they exhibit even one symptom in a list of symptoms (called *contraindications*). Yet vaccines are legally required anyway.
 - summarized from Physicians and Surgeons Fact Sheet on Mandatory Vaccines, Association of American Physicians and Surgeons aapsonline.org/testimony/mandvac.htm
- ◆ In 2015, babies and children in La Pimienta, Mexico received inoculations for tuberculosis, rotavirus and hepatitis B, as ordered by the Mexican Social Security Institute. A full 75% of these children either died or were hospitalized.

- ◆ The British newspaper *Independent* reported that between January 1, 2005 and April 22, 2015, almost 22,000 injuries and deaths from vaccines (mostly for influenza and human papillomavirus) had been reported to public health authorities.

- ◆ In 2014, fifteen high school students in Falmouth, Massachusetts became ill with whooping cough. The state of Massachusetts allows parents to exempt their children from inoculations on philosophical grounds, so it was assumed that the number of outbreaks had increased because exemptions had increased by 5% from the previous year. However, a doctor was quoted as saying that all of the children who’d contracted whooping cough had been inoculated. No one questioned this apparent anomaly.

- ◆ *2009: Doctors in Germany.* “Fredrich Hoffmann, head of Germany’s national vaccine commission, has told doctors that they should give the untested ‘swine flu’ jab to their patients no matter what . . . However, doctors in Germany are refusing to be bullied by the authorities in league with big pharma into rolling out a ‘swine flu’ jab campaign that will make billions for vaccine companies. Dr Jürgen Seefeldt, a specialist in internal medicine from Paderborn, sent an open letter to Dr Susanne Stöcker, an official from the German drug regulator, the Paul Ehrlich Institute, pointing out . . . her statement in the media that the ‘swine flu’ jab was not risky was an ‘infamous lie.’”³⁵⁰
- ◆ *2009: Polish Health Minister Eva Kopacz.* During a heated debate about the swine flu vaccine, she told Parliament that as a qualified family doctor with more than 20 years of experience, she could not and would not authorize the use of vaccines on millions of people as long as: there was no disclosure about the amounts of adjuvants and other ingredients in the formulas, the vaccines were inadequately tested (only a small number of healthy people were given the jab), and there was almost no information about the dangers (“side effects”) of the inoculations. Why should she subject the people of Poland to an unknown medication when the pharmaceutical companies did not want to take responsibility for any negative effects? She noted that governments in Western Europe, including Poland, “had signed secret agreements with pharmaceutical companies,” but “the secret contract that the Polish government was supposed to sign with pharmaceutical companies had more than 20 clauses which are against the law.” The prosperity of the Polish people, she said, was “more important to her than the profits of Big Pharma.” Finally, she pointed out, “the regular flu was much more common and damaging than the swine flu—“yet no pandemic had ever been declared over the seasonal flu.” Furthermore, all 193 people who were presumed to have had the swine flu, had survived.”³⁵¹
- ◆ *2011: Doctors and Nurses in the UK.* Even after years of urging health care providers to be vaccinated, Britain’s National Health Service still couldn’t convince them—and worried about their low inoculation rate. “No doctor among the 41 associated with direct patient care working for Derby City primary care trust was vaccinated, while in Luton PCT just one of 145 doctors received a jab (0.7%) and in Heart of Birmingham PCT five of 328 doctors were vaccinated (1.5%). . . . Nurses had similarly low rates. Just 3.7% of nurses at Suffolk mental health partnership got vaccinated . . . Fewer than one in 10 frontline health workers in some trusts were vaccinated. . . . Dame Sally Davies, the chief medical officer for England, recently criticised NHS staff who did not have the jab. ‘It is very selfish not to be vaccinated.’”³⁵²
- ◆ *2012: Various Health Workers in the UK.* Many health workers who trust the damage that they see with their own eyes, rather than the pro-vaccine slogans that they constantly hear, do not want to be vaccinated. The article, “Most UK Medics Refusing Flu Vaccines—UK’s New Chief Medical Officer Resorts To Bullying,” stated in part: “NHS [National Health Service] figures reveal only 34.7% of staff were vaccinated last year. . . . the UK’s Chief Medical Officer and other health officials have resorted to bullying NHS staff into taking the vaccine when it is known to be ineffective . . . and when vaccine safety data is being suppressed.”³⁵³
- ◆ *2012: Health Workers in Switzerland.* They refused vaccines for themselves and hesitated to administer them to those in their care. A Geneva hospital study “showed that many health care personnel thought of seasonal flu as ‘a benign disease not really requiring any special [prevention] effort.’ . . . [Homeopathic physician Pascal] Büchler says . . . ‘vaccines against seasonal flu have been shown to be ineffective for elderly people, who are also the greatest risk group.’ Büchler also questions the ‘alarming’ campaign brought by the Federal Office of Public Health. He refers to a large-scale epidemiological study, by American researcher Tom Jefferson, which concluded that only five to seven per cent of people displaying flu-like symptoms were actually infected with the virus. ‘If we transfer these figures to Switzerland, 75 people would be the accurate figure for deaths caused by influenza, and not 1,500 as the Office for Public Health would have us believe,’ Büchler says. . . . In 2010, the World Health Organisation (WHO) was accused of dramatizing worldwide influenza cases [because] . . . many countries had signed contracts with a stipulation to automatically buy vaccines when the WHO gave the highest alert level.”³⁵⁴
- ◆ *2012: Italian Ministry of Health.* “The Italian Ministry of Health prohibited the use and sale of four influenza vaccines produced by the pharmaceutical company Novartis. . . . The main risks involved are the serious side effects that may be caused by these flu vaccines. . . . They also announced the recall of 2.3 million doses of the Inflflexal V flu vaccine. ‘Potential danger’ to health was claimed for the recall.”³⁵⁵

- ◆ *2014: Dr. Bernard Dalbergue, a former pharmaceutical industry physician.* He stated that Gardasil® was “useless,” and that “decision-makers at all levels are aware of it. . . . [It] has absolutely no effect on cervical cancer” and “the very many adverse effects which destroy lives and even kill, serve no other purpose than to generate profit for the manufacturers.”³⁵⁶
- ◆ *2014: Dr. Suzanne Humphries, board certified in nephrology.* Pro-vaccine when first starting her practice, she changed her mind after seeing too many injuries. “Vaccines do not increase the health of a human. There is nothing in a vaccine that our bodies actually require. . . . [and there is] no nutritive effect. . . . I take really good care of my immune system.”³⁵⁷
- ◆ *2015: Former Pharmaceutical Sales Representatives (from Merck).* Scott Cooper and his wife decided against inoculating their son (born 1991). In an Internet video, Scott said that his son was rarely sick and was always healthier than his vaccinated peers. Before vaccine manufacturers were granted legislative protection, Cooper revealed, most of the lawsuits against Merck were because of its vaccine division.³⁵⁵ Brandy Vaughan, founder of the nonprofit Council for Vaccine Safety, also spoke against mandatory vaccinations. “The pharmaceutical company is using vaccines as a new driver for profit. This is really what’s behind the mandatory vaccination bills.”³⁵⁸ After her house was vandalized and her phone lines were tapped, she began repeatedly and publicly announcing that she would never commit suicide, especially as she was responsible for a young son whom she loved. In 2020 authorities proclaimed her unexpected death a suicide, but friends and colleagues said that she had been murdered.³⁵⁹
- ◆ *2021: Dr. Robert Malone, inventor of the mRNA and DNA vaccine core platform technology on which the Covid-19 “vaccines” are based.* He warned the FDA that the spike proteins—which the injections instruct the body’s own cells to create—are dangerous, as they are biologically active and travel throughout the body.³⁶⁰ The FDA ignored his appeals to not use the technology.
- ◆ *Ongoing: Health Practitioners, United States only (not mentioned elsewhere).* John Classen, MD (immunologist); Philip Incao, MD (general and children’s medicine); Mary Megson, MD (pediatrician); Meryl Nass, MD (internist); Lawrence Palevsky, MD (pediatrician); Sherri Tenpenny, DO; Jack Wolfson, MD (cardiologist), Rashid Buttar, DO.

Not surprisingly, statistics show that medical doctors “are the least inoculated group in the United States.”³⁶¹

Evolving Bacteria Outsmart Vaccines

Just as bacteria have adapted to antibiotics—so well, that they have become resistant—bacteria are now adapting to the effects of vaccines. The abstract of an article in a 2015 issue of *Journal of Infectious Diseases* states: “A worldwide resurgence of pertussis has been linked . . . to the use of acellular pertussis vaccines and the evolution of *Bordetella pertussis* away from vaccine-mediated immunity.”³⁶² In other words, the bacterium is responding in a self-protective way to the vaccine. The vaccine, instead of stimulating the human body to become immune to the bacteria, is stimulating the bacteria to adapt, so that it becomes immune to any attempts to eradicate it.

In response to the article, Dr. Joseph Mercola commented: “In 2013, the FDA discovered that while the whooping cough vaccine may reduce symptoms in those who are vaccinated . . . [it] does not prevent infection and transmission of the disease. In fact, you can get a series of pertussis shots and still become an asymptomatic carrier who is contagious and can spread the disease to others without even knowing it. That study effectively shattered the long-held illusion of vaccine-induced herd immunity.”³⁶³ There are over three hundred different strains of influenza, and a typical flu vaccine only targets the few that researchers guess might be present during the next flu season. To “remedy” this, scientists are now trying to target tiny portions of a single virus.

Typically, flu vaccines are created to stimulate the production of antibodies in response to the main protein of a flu virus: *hemagglutinin*, the lollipop-shaped structure on a virus’s outer shell. The head of hemagglutinin protein tends to mutate, while the larger stalk or stem remains fairly constant. Attempting to create a universal flu vaccine covering *all* influenza strains, scientists have removed the head and focused on the stalk. The theory is that when the body is injected with the stalks of just a few strains—presumed to be similar to each other and thus stable—the human will produce cross-reactive antibodies to *all* flu viruses.

However, in research with pigs (who in many ways react similarly to humans), the reality is different from the theory. Pigs injected with “stalk” vaccine for one virus, and then exposed to a different viral strain, have actually been *more* susceptible to severe respiratory disease than pigs *who are not vaccinated at all*. Research in many countries, using different animals, has yielded similar results.

Rather than splice viruses—which create even more elaborate and dangerous vaccines that don’t work—why not focus on helping the body simply, with natural substances? Or is it more fun to micromanage?

Vaccine Alternatives and Detox

In this technological age, people are becoming sicker—not only due to increasing numbers of antibiotic-resistant bacteria, but also the unprecedented increase in worldwide travel. More foreign ports means exposure to unfamiliar pathogens to which travelers haven't developed a natural immunity. This is one reason that doctors push so hard for inoculations before people visit foreign countries.

Vaccines encourage immunity only in theory. If we really want a healthy immune response, it makes no sense to inject fragmented or altered pathogens, bodily wastes, heavy metals, chemical preservatives, and other poisons into an already overloaded body. It does make sense to gently encourage immunity using ingredients and protocols that are compatible with the body's processes. If you want to stop inoculations for yourself and your children, it's helpful to know what the alternatives are.

Also, what do you do *after* you've been jabbed? If you are suffering from toxic effects? Or, what if you're lucky and feel okay after inoculation, but do research and decide that even though you won't accept any more vaccines, you still need to eliminate the poisons from your recent jab? This is when *detoxification* is needed to help the body eliminate dangerous and poisonous substances.

As it turns out, the safest and most effective “vaccine substitutes”—ingredients that encourage a natural healing response—are useful not only for when you become ill, but also for detox. I'll discuss just a few here. (Detox protocols are addressed in detail in Chapters 3 and 5.)

The information is *out there*. Brilliant scientists, physicians, and researchers without financial ties and agendas have weighed in and presented their concerns about vaccine safety and efficacy. However, the average citizen resists and clings to a hyper-simplified, seemingly “safe” stance. . . .

I understand now that my collection of PubMed articles substantiating concerns about inefficacy, neurological, autoimmune, and fatal risks of these poorly conceived and anachronistically relevant immune modulators is not meaningful to someone who is not interested. The questions raised by this information are not provocative to someone who needs, above all, to believe that the government, the CDC, and doctors mean well, are doing their due diligence, and that they are holding themselves to a basic standard of ethical delivery of healthcare. They are not meaningful to someone who needs to outsource their power.

Colostrum and Proline-Rich Polypeptides

The first “vaccine” that most humans and other mammals receive in life is a natural one, so in many ways it's the first and obvious choice for strengthening the immune response. This amazing substance is *colostrum* (and one of its extracts, discussed in a moment). Colostrum, sometimes called “the first milk,” is a yellowish sticky fluid rich in antibodies that's secreted by the mother's breasts just after she gives birth. It's produced for the first five days after birth, after which it becomes “transitional milk,” and is then replaced by “regular” milk—itsself rich in fats, proteins and essential nutrients—after a few weeks. All of the antibodies that the mother has created during her life, as a result of exposure to various pathogens, are conveyed to the infant through nursing.

This is why it's so important for babies to nurse. (The Weston A. Price Foundation has excellent recipes for natural liquid formulas if nursing isn't possible.) According to the La Leche League, an international organization that encourages women to breastfeed and teaches them how:

Colostrum actually works as a natural and 100% safe vaccine. It contains large quantities of an antibody called secretory immunoglobulin A (IgA) which is a new substance to the newborn. Before your baby was born, he [sic] received the benefit of another antibody, called IgG, through your placenta. IgG worked through the baby's circulatory system, but IgA protects the baby in the places most likely to come under attack from germs, namely the mucous membranes in the throat, lungs, and intestines.

Colostrum . . . [is vital for] the baby's gastrointestinal tract. A newborn's intestines are very permeable. Colostrum seals the holes by “painting” the gastrointestinal tract with a barrier which mostly prevents foreign substances from penetrating and possibly sensitizing a baby to foods the mother has eaten. Colostrum also contains high concentrations of leukocytes, protective white cells which can destroy disease-causing bacteria and viruses.

The colostrum gradually changes to mature milk during the first two weeks after birth. . . . the concentrations of the antibodies in your milk decrease [but]. . . The disease-fighting properties of human milk do not disappear with the colostrum. In fact, as long as your baby receives your milk, he will receive immunological protection against many different viruses and bacteria.³⁶⁴

Colostrum (and later, mother's milk) is considered a perfect food. It's antiviral, antibacterial, antifungal, and

antiparasitic. It promotes bone density, skin elasticity, stamina, and good digestion. It builds muscles and also repairs cartilage and nerves. And it's anti-aging. What colostrum can help correct is almost unlimited.

The most developed country in the world that heavily pushes vaccines—the US—is also one of the nations that provides the least support for breastfeeding. Few workplaces provide rooms where women can breastfeed or pump their milk. (A nursing mother must extract her milk regularly, or she stops producing it due to the lack of nipple stimulation.) In parks, restaurants and other public spaces, women are discouraged from nursing their babies—either psychologically (shaming and ridicule) or legally (laws that make it a crime for women to expose their breasts in public, even to nurse). Often, where it's legal for women to openly breastfeed, they are told to leave.

The medical establishment advises women not to breastfeed infants who are about to be inoculated because breastfeeding “interferes” with vaccines—rather than perceiving that vaccines interfere with the body's natural immunity! In 2010, the *Pediatric Infectious Disease Journal* published an article with the astonishing (and revealing) title of “Inhibitory effect of breast milk on infectivity of live oral rotavirus vaccines.” The authors compared how the breastmilk from women in India, Vietnam, South Korea, and the US affected a rotavirus vaccine. (The milk of Indian women conferred the highest immunity protection; the milk of US women, the lowest. Diet was presumed to be a factor.) The authors emphasized: “Strategies to overcome this negative effect, such as delaying breast-feeding at the time of immunization, should be evaluated.”³⁶⁵ Incredibly, the ability of breastmilk to confer immunity was promoted as a “negative effect”! A rebuttal to this article by Kristen Michaelis, called “CDC Advises Delayed Breastfeeding to Boost Vaccine Efficacy,” states in part:

Ten researchers from the CDC's National Centers for Immunization and Respiratory Disease (NCIRD) released a paper arguing that because the immune-boosting effects of breastmilk inhibit the effects of the live oral rotavirus vaccine, nursing mothers should delay breastfeeding their infants.

This . . . is the kind of convoluted logic that permeates the pharmaceutical industry. . . . Do they not realize what they have stumbled upon? *In demonstrating that breastmilk counters the live vaccine, they've shown that breastmilk counters the virus.* . . . Yet instead of recommending that the best way to fight this disease in infants is to encourage mothers to breastfeed, they're recommending that mothers refrain from breastfeeding so that the vaccine can work! . . .

Unvaccinated Children Are Healthier Than Their Vaccinated Counterparts

Considering the control that Big Pharma exerts over most medical journals—and the hostile (and unscientific) defense of vaccines escalating to the point where some people are publicly demanding the death of “anti-vaxxers”—studies comparing the health of vaccinated and unvaccinated children are either unknown, or aren't cited.

Finally, in 2017, the *Journal of Translational Science* had the courage to publish two studies. “Preterm birth, vaccination and neurodevelopment [NDD] disorders: a cross-sectional study of 6- to 12-year-old vaccinated and unvaccinated children,” revealed that vaccinated term birth babies had a 2.7 times greater risk of NDD (which could manifest as a learning disability, ADHD or autism), while prematurely born infants who were vaccinated had a *14 times greater risk* of developing NDD. Even *full* term, vaccinated children had a statistically significantly higher risk of developing NDD than full term or preterm children who weren't vaccinated. “The results of this pilot study,” the authors wrote, “question the safety of current vaccination practices for preterm infants”³⁶⁶—and, I would add, for everyone else as well.

“Pilot comparative study on the health of vaccinated and unvaccinated 6- to 12-year-old U.S. children” dealt with 666 older, homeschooled children. In contrast to the uninoculated, inoculated children had 30 times more incidents of hay fever, 300% more ear infections, and a 340% increase of pneumonia. In the area of learning disabilities (a quadrupled risk), the inoculated were more than three times likely to develop autism and 300% more likely to be diagnosed with ADHD. Overall, they were 250% more likely to be diagnosed with a chronic illness. The authors wrote: “The strength and consistency of the findings, [and] the apparent ‘dose-response’ relationship between vaccination status and several forms of chronic illness . . . all support the possibility that some aspect of the [vaccination] program could be contributing to risks of childhood morbidity.”³⁶⁷

One study conducted in New Zealand decades ago has now surfaced. In 1992, the Immunization Awareness Society (IAS) compared the health of vaccinated and unvaccinated children. Vaccinated children were far more likely to suffer from asthma, eczema, ear infections, hyperactivity, and tonsillitis. Not one of the unjabbed children had epilepsy or underwent a tonsillectomy, compared to the inoculated children (almost 2% had epilepsy and over 5% had surgery to remove tonsils).³⁶⁸

A full 43% of American children suffer from at least one chronic illness. They are four times more likely to be ill than their parents. Are vaccines helping?

[This] proves just how effective breastmilk can be! . . . Clearly, they have one goal in mind: to sell more vaccines. . . . if you are healthy, they don't make any money off of you. [emphasis added]³⁶⁹

The National Health Service from Great Britain (probably unintentionally) supports Michaelis's point:

Babies under six months old are not routinely given the MMR vaccine. This is because the antibodies to measles, mumps and rubella passed from their mothers at the time of birth are retained and can work against the vaccine, meaning it's not usually effective. However, this means the risk of any side effects is even lower among these younger babies, because the antibodies passed from the mother stop the viruses in the vaccine from growing. These maternal antibodies decline with age and are almost all gone by the time that MMR is normally given—around one year old.”³⁷⁰

People need to understand that when they're deciding between breastmilk and formula, they're not deciding between Coke and Pepsi. . . . They're choosing between a live, pure substance and a dead substance made with the cheapest oils available.

—Chele Marmet
founder of the World Alliance for Breastfeeding Action, who developed a technique in the 1970s to encourage the milk ejection reflex (MER) so nursing mothers could manually express more breastmilk

This statement from the NHS is misleading. One-year-olds lose the antibodies acquired from their mothers only if they stop nursing! As the La Leche League makes clear, ordinary breastmilk also provides immunity, although in lesser concentrations. Is the British National Health Service trying to scare parents into vaccinating their children? Also, as mentioned earlier, *the absence of antibodies does not mean a lack of immunity*. If antibodies are present, this means only that the system has been *recently* challenged by a particular pathogen. Immunity isn't static.

Moreover, if both mother and child are exposed to the same pathogens—and it's reasonable to assume that they will be—the mother creates a custom, environmentally specific immune milk for her infant. Pediatrician Bob Sears, father of eight children, writes:

Even babies who continue to nurse into toddlerhood benefit from the many immune factors in their mother's milk. . . . When a baby is exposed to a new germ, mother's body manufactures antibodies to that germ. These antibodies show up in her milk and are passed along to her baby. Many a nursing mother can tell the story of the entire family—dad, mom, siblings—coming down with the flu and the

nursing baby having the mildest case, or not getting sick at all. When mother comes down with a bug, the best thing she can do for her baby is to keep breastfeeding. . . .

Pioneers in breastfeeding research stated that breastfed infants are “biochemically different.” This difference in body chemistry may be the reason they are healthier. While babies are breastfeeding, they have fewer and less serious respiratory infections, less diarrhea, and less vomiting. When breastfed babies do become ill, they are less likely to become dehydrated and need hospitalization. . . . Studies have found that the benefits of breastmilk protect against a wide variety of other diseases. Here's a partial list: *Haemophilus influenzae* type B, pneumonia caused by *Streptococcus pneumoniae*, meningitis, infant botulism, urinary tract infections, cholera, salmonella, *E. coli* infections, [and] respiratory syncytial virus.³⁷¹

Suppose you are not a nursing infant (a realistic assumption if you're reading this book), and you want extra immunity now, as an adult. What can you do?

Whereas the fat and protein content of milks vary greatly between mammalian species, fortunately the immunity-building colostrums are universal. Whether from a cow, goat, camel, sheep, water buffalo, horse, dog, cat or other mammal, the beneficial molecules in colostrums are the same. This is why immunity can be conferred from one species to another, including humans. The world's commercially produced colostrum typically comes from cows; and the best and cleanest is from New Zealand, where rich, pesticide-free grasslands provide high quality grazing for the naturally raised cattle. The colostrum is collected after the calves have nursed first, usually for about the first 12 to 18 hours after birth. (If calves don't nurse, they always die.)

Colostrum, which as mentioned earlier contains immune factors that are even more concentrated than in breastmilk, is antibacterial, antiviral, antifungal, and antiparasitic. It promotes bone density, skin elasticity, stamina, and good digestion. It builds muscles and repairs nerves and cartilage. With virtually unlimited benefits, it both prevents illness and helps with detoxification. Just a few of the many valuable substances in colostrum are:

- ◆ *Lactoferrin*. A protein found in all mucous secretions of the body, lactoferrin is an all-purpose germicide. It kills pathogens by blocking their access to iron (which they need to reproduce), by preventing them from attaching to the host body's cells, and by binding to the outer membranes of pathogens, which causes them to burst. Lactoferrin is also anti-inflammatory, an antioxidant, and promotes the growth and activity of white blood cells.
- ◆ *Growth Factors*. Besides protecting the gut of the newborn and repairing the intestinal tract in adults and children, they regulate the growth of cells. This helps to heal wounds, broken bones, and injured ligaments and tendons.
- ◆ *Vitamins, Minerals, and Enzymes*.
- ◆ *Friendly Flora*. The probiotics help with digestion and immunity.
- ◆ *Proline-rich Polypeptides (PRPs)*, *small signaling molecules in the form of amino acid strings (sometimes also called transfer factors)*. These are the very best component of colostrum for concentrated immune protection. A detailed discussion is below.

Thinking that baby formula is as good as breast milk is believing that thirty years of technology is superior to three million years of nature's evolution.

Andrew Keech, PhD, is the former owner of a huge colostrum manufacturing plant in Phoenix, Arizona, US. The factory contains highly sophisticated equipment to transform the liquid colostrum into a powder that retains all the benefits of the original liquid. The powder is either sold in bulk in containers or put into capsules. Keech has developed a method of extracting just the PRPs (and other, single components) from colostrum without damaging the effectiveness of the delicate molecules. His technical but understandable, color-illustrated book, *Peptide Immunotherapy, Colostrum: a Physician's Reference Guide*, is comprehensive, heavily referenced, and well worth reading if you want to know more about the history, chemistry, and biological and physiological effects of these remarkable substances in colostrum. In it, Keech writes that proline-rich polypeptides are the “true gem” in colostrum, because they “modulate, balance, regulate or initiate indirectly most of the biochemical processes in the mammalian body. They are probably the most significant natural substances in the human body relating to the immune system.”³⁷²

Be aware that there's a difference between *boosting* the immune response and *modulating* or *regulating* it. Pharmaceuticals artificially boost or amplify the activity of the immune cells. But this boost forcibly pushes the body

into an unnatural, hypervigilant state—which causes lots of excess inflammation and faulty biochemical signaling, leading to autoimmune disorders. Colostrum, on the other hand, *regulates* or *balances* the immune cells. A genuinely regulated—that is, normal—immune response will become augmented or intensified if it's lethargic. But it will also become calmer and subside in intensity if it's too active. Colostrum, with its immune-regulating PRPs, never push the immune response in a direction that's not beneficial to the body.

PRPs alone confer more immune cell support than a comparable amount of colostrum (which contains fewer PRPs by volume). Therefore, pure PRPs may be preferred by people with severe illnesses. (Sometimes, people sensitive to dairy also choose PRPs instead of colostrum, which may cause reactions.) One serving of PRPs costs more than a serving of colostrum; but it's concentrated, so you get what you pay for. PRPs and colostrum have been used for every conceivable type of infection—including Epstein-Barr virus, Lyme disease, all strains of influenza—as well as cardiovascular and heart disease, inflammatory bowel conditions and leaky gut, all types of brain damage, and cancers. The list is endless. Some ranchers deliberately expose their cows to virulent pathogens and later collect their colostrum, which is given to humans infected with the same pathogens. This is a safe way to administer antibodies, similar to what mothers do when they nurse their babies. Lyme disease is sometimes eradicated by ingesting colostrum from Lyme-infected cows.

PRPs were originally discovered in 1949 by Dr. H. Sherwood Lawrence. Seeking the means by which tuberculosis immunity was conveyed from a person who had recovered to someone who was ill, Dr. Lawrence analyzed the tiny fractional components of lymphocytes (a type of white blood immune cell), and discovered PRP molecules. PRPs, he learned, were able to transfer a balanced immune response from one person to another. Then in the mid-1980s, two researchers surmised that PRPs might also be present in colostrum. (A confirmation of this discovery was awarded a patent in 1989.) Typically, cows are the most plentiful source of colostrum because they're large and easy to raise.

How exactly do PRPs work? Keech explains the details:

PRPs directly support the natural killer (NK) cells of the immune system. Natural killer (NK) cells provide the front line of defense specially equipped to locate and kill disease cells. NK

Vitamin A Helps Repair Vaccine Damage

Developmental pediatrician and autism specialist Mary Megson discovered that vaccines impair the memory of T cells and block the Vitamin A pathways in the brain. She recommends a daily intake of cod liver oil.

- ◆ 2–5 year olds: ½ teaspoon (or 2500 IU of Vitamin A)
- ◆ 5–10 year olds: ¾ teaspoon (or 3750 IU of Vitamin A)
- ◆ 10–12 year olds: 1 teaspoon (or 5000 IU of Vitamin A)
- ◆ Infants younger than 2 years old: less than 1/5 of a teaspoon either in their bottle or rubbed on the belly (the oil is easily absorbed through the skin)

Dr. Megson reports that children have responded well, enjoying improved eye contact, decreased asthma symptoms, better language comprehension and verbal skills, and better overall health. Infants respond even faster than older children.

cells attach to the surfaces of foreign substances or their outer cell wall and inject a chemical “grenade” (granule) into the interior. Once inside, the granules explode and destroy the foreign invader within five minutes. The NK cell itself remains intact and moves on to destroy the next immune attacker.³⁷³

I want to make one more, very important point. Back in 1950 and then in 1962, articles in two medical journals reported that Albert Sabin, the inventor of the oral polio vaccine, used antibodies from bovine colostrum for his first inoculations. Note the revealing titles: “Antipoliomyelitic substance in milk from human beings and certain cows,”³⁷⁴ and “Antipoliomyelitic activity of human and bovine colostrum and milk.”³⁷⁵ The substance that prevented polio was simple, and it already existed! But instead of using what was readily available in its natural state, Sabin chose to fabricate an unnecessarily complicated and dangerous pharmaceutical vaccine.

Dr. Andrew Keech, who grew up in New Zealand on a dairy farm, was blessed to drink unprocessed milk and (when available) colostrum, straight from the cows. He never got sick. People raised in cities and suburbs, divorced from the land, usually aren’t taught that the cures to what ails us already exist. The field of holistic health encourages us to return to the best of our roots.

I have devoted so much space to colostrum because, more than any other substance, it’s the quintessential natural “vaccine” that’s made especially for us, and is ready the moment we’re born. No synthesized drug can match its benefits. Should we need colostrum again at any time, we can take it—and enjoy true healing. But the results are not due to magic. They are grounded in biology.

Glutathione

The glutathione molecule is a *tripeptide* molecule, consisting of three *peptides*, or amino acids (the building blocks of protein)—L-cysteine, L-glutamine, and glycine. Glutathione helps build and repair tissues of the body, making it an ideal anti-aging ingredient. A key immune cell builder, it allows the white blood cells to remain viable for long periods of time and helps the body detoxify from various poisons, including heavy metals. Glutathione also protects every cell from damage and oxidative stress due to *free radicals* (discussed in detail in Chapter 3), giving it a well deserved reputation as the ultimate antioxidant.

In February 2000, an article appeared in the *Indian Journal of Medical Sciences*, “Glutathione levels in health and sickness.”³⁷⁶ The authors observed that a group of people with chronic illnesses—including heart disease, diabetes, chronic kidney failure, cataracts, and leukemia—had very low glutathione levels compared to a control group. They (reasonably) concluded that oxidative stress plays a huge role in illness, and recommended antioxidants as a viable medical therapy.

Glutathione improves the entire body, including cardiovascular system, brain and nerve tissue, immune cells, and muscles. This is why people use glutathione for such a variety of conditions: autism, dementia, Parkinson’s, heart disease, cancers, all kinds of infections, muscle damage, fibromyalgia, fatigue and low energy. Insufficient amounts of this compound even play an important role in autism, according to a December 2004 report issued by the independent Environmental Working Group:

Autistic children had less glutathione, an antioxidant that helps rid the body of toxic metals, when compared to a sample of healthy children. The study, led by Jill James, PhD, a professor of biochemistry and pediatrics at the University of Arkansas for Medical Sciences, found that a glutathione deficit “may contribute to the development and clinical manifestation of autism.”³⁷⁷

Glutathione is produced naturally by the liver, as long as two conditions are met. One, the liver must be relatively clear of toxins so it’s not overloaded and can do its manufacturing job. Two, the body must have the raw materials to make glutathione. Meeting the first condition can be a challenge. If the liver is too clogged to produce glutathione, more toxins accrue in the body—but the more toxins that accrue in the body, the more intensely glutathione is needed to help with detoxification! This is why people often must rely on external supplies of glutathione to increase their internal levels.

Which brings me to the second condition. There are two ways to increase glutathione levels: by providing the body with enough of the required raw materials so it can make it, or by taking glutathione supplements.

Foods that help either boost or maintain glutathione levels include some fruits (grapefruit, cantaloupe, peach, watermelon and strawberries), and vegetables (asparagus, avocado and spinach). Vegetables that contain lots of sulfur are especially helpful: onions, garlic, broccoli, kale, collards, cabbage, cauliflower and watercress. Raw eggs and grass fed meats contain sulfur. Whey, a protein formed when cheese is made, is especially high in sulfur, and it's available in powdered form at any health food store. You will need *cold-pressed* whey, which means that the proteins have not been *denatured*, or broken down by high heat during processing.

In the herbs department, milk thistle is popular and very effective for the liver. Often known by the name of its most active chemical compound, *silymarin*, milk thistle helps prevent glutathione from being depleted in the liver. It also helps protect the liver from solvents and other chemicals. A less easily obtained, but very powerful Chinese herb is *Platycodon grandiflorus*, also known as Balloon Flower Root or jiegeng. This herb is used a great deal in Chinese medicine because of its anti-inflammatory properties and its ability to increase intracellular glutathione.

A few commonly available nutritional supplements boost glutathione levels. Alpha Lipoic Acid (ALA) not only increases the amount of intracellular glutathione, but it's a powerful antioxidant that makes other antioxidants (such as Vitamin C and Vitamin E) more potent. Another vital nutrient, available in powder or capsule form, is N-Acetyl-Cysteine (NAC). Derived from the amino acid L-cysteine, NAC is a *precursor* of glutathione: once in the body, it's rapidly transformed or metabolized into glutathione, a more chemically stable compound. (NAC is so effective, it has even been approved by the FDA as a treatment for aspirin overdose.) Selenium, a powerful essential trace mineral, helps the body recycle and produce more glutathione.

A group of three nutrients, which work together and are considered perhaps the most critical to support the body's own glutathione production, are the biologically active form of folate (5-methyltetrahydrofolate, or simply methylfolate), the biologically active form of Vitamin B6 (Pyridoxal 5-Phosphate, or P-5-P), and the biologically active form of Vitamin B12 (methylcobalamin). These are discussed in great detail in Chapter 3.

What about supplementing with glutathione itself? Some glutathione supplements are worthless because, as a small molecule, glutathione is easily digested by the stomach acid and is therefore not available to the rest of the body's cells. This may be why many establishment and holistic medical personnel advocate the intravenous (IV) delivery of glutathione. However, injectable nutrients must be administered by a licensed health professional, and are therefore costly. Thus, there may be a bias to the claim that only IV glutathione is well absorbed.

At least one form of oral glutathione is highly effective: *reduced* glutathione. Reduced glutathione bypasses the

digestive processes intact, and is easily absorbed by every cell—including those of the eyes, liver and brain—if it's accompanied by suitable biochemical transporters. A few proteins act as glutathione transporters, one of which is disulfide bond cysteine. Articles that discuss the bioavailability of ingested glutathione include "Glutathione Transporters,"³⁷⁸ "Enhanced Glutathione Levels in Blood and Buccal Cells by Oral Glutathione Supplementation,"³⁷⁹ and

"Plasma membrane glutathione transporters and their roles in cell physiology and pathophysiology."³⁸⁰

In the 1970s, a doctor discovered a special whey protein, gamma-glutamyl-cysteine (GGC), which is a vital precursor to glutathione and is easily converted in the body. Whey, rightly promoted for its immune-supporting role, is generally well tolerated; but those who are especially sensitive to dairy may prefer another form of oral glutathione, *liposomal* glutathione. Here, the glutathione molecule is surrounded by a single thin layer of lipids (oils), which allow the glutathione to survive stomach acid and enter the cells directly. (Chapter 3, **Nutritional Supplements**, contains a recipe for making liposomal Vitamin C. This can be tried with ordinary, non-reduced glutathione as well.)

One novel way of getting glutathione into the body is in the form of patches. One company manufactures round adhesive bandages, a little less than 1.5 inches, that are placed on the skin over acupuncture points. These patches contain homeopathic remedies and other substances that don't penetrate the pores of the skin, but instead, transfer the *energy* of their ingredients to deep inside the body, thus inducing the production of endogenous glutathione.

Glutathione is essential for disease prevention. Vaccines cannot compare to glutathione's superior benefits and biocompatibility. Glutathione is essential for detoxifying from any poisons. And it's impossible to take too much.

One more thing. Colostrum contains glutathione.

Vitamin C

Vitamin C is most commonly known as *ascorbic acid*, (which is shorthand for “hydrogen ascorbate”). However, this vitamin also comes in the form of alkaline mineral ascorbates: sodium, calcium, magnesium, and potassium ascorbate. The ascorbate ion always attaches to another ion; hence, the compound name.

Vitamin C is a critically important nutrient. Involved in the growth and repair of every tissue, it’s a component of *collagen*, a protein found in skin, cartilage, tendons, ligaments, blood vessels, portions of the nerves and eyes, and the connective tissue membrane (*fascia*) that covers the muscles and spreads in a complex network throughout the entire body. These structures don’t work properly if there’s not enough Vitamin C to help build them. Vitamin C heals wounds and helps repair and maintain bones and teeth. As one of the top antioxidants, it protects DNA from damage and helps the body remove heavy metals and other toxins. It protects the cell membranes from toxic wastes and destruction. And it helps the body fight all types of infections, including cancers.

A May 2013 issue of *Nature Communications* published an article, “Mycobacterium tuberculosis is extraordinarily sensitive to killing by a vitamin C-induced Fenton reaction.”³⁸¹ (A *Fenton reaction* is the chemical catalyzation of the production of hydrogen peroxide. Hydrogen peroxide scavenges various pollutants including formaldehyde, which makes Vitamin C so helpful for detoxifying from the effects of vaccines.) Vitamin C cannot eradicate all pathogens, but it does help with many viruses and bacteria, including *Herpes*, *H. pylori*, influenza, and more—even Ebola.

Nobel Prizewinner Linus Pauling, PhD, helped make the public aware of ascorbic acid’s many features. In a 1992 issue of *Journal of Orthomolecular Medicine*, he wrote, with co-author Matthias Rath, “Ascorbate deficiency is the precondition and common denominator of human CVD [cardiovascular disease].”³⁸² We are commonly taught that a long term Vitamin C deficiency results only in scurvy, a condition of overall weakness and tenderness of the tissues, bleeding and bruising of the mucous membranes and skin, brittle bones, and anemia (insufficient amounts of red blood cells). But before the body reaches this point of severe deficiency, a tremendous amount of damage has

already occurred. This is because Vitamin C is critical to so many structures and functions of the body. It’s so important, in fact, that despite its easy availability, Vitamin C is undervalued and underutilized. It may be one of the most publicized, yet least understood, nutrients.

Because Vitamin C is water soluble, it doesn’t accumulate in the fat cells. It’s excreted daily by the body in urine and sweat, and therefore must be replaced each day. Replenishing this most important nutrient is even more critical because unlike most mammals, which produce ascorbic acid in their own bodies, humans

don’t have this capacity. Even high quality foods don’t supply us with nearly enough; and Vitamin C is destroyed by heat, so supplementation is essential. The benefits of Vitamin C are increased when taken with Vitamin E.

The medical establishment claims that few people are deficient in Vitamin C. However, the number of illnesses and degenerative conditions suffered by a majority of the population

prove that these claims are false. Dr. Pauling himself took what some consider to be massive doses: at least one gram daily (1 gm = 1,000 mg), in staggered 100 mg amounts throughout the day. The average adult, he said, required between 10 and 12 grams daily. The body governs the amounts, Pauling taught us, and its rule is simple. If you develop diarrhea, take less. If you don’t develop diarrhea, take more. Decrease a bit when you just reach the point where you start to experience loose stools.

Aside from diarrhea—which is the body’s way of indicating that more ascorbic acid is being ingested than what the system can handle at the moment—it’s impossible to ingest too much. For immune support for adults, many sources recommend 2,000 mg (2 gm) per day. Owen R. Fonorow of The Vitamin C Foundation mentions that an orthomolecular practitioner might suggest 5,000 mg of ascorbic acid daily. Especially for people who are ill, this may be a more suitable figure than a lesser amount, considering (as Pauling pointed out) that about half of the Vitamin C taken orally is broken down before reaching the cells, and is thus biologically unavailable.

One more thing. Vitamin C comes in four shapes whose atoms are arranged differently (some being mirror images of the others). The only form that can help build collagen is the L-ascorbate shape. Therefore, make sure you take this one, and that it’s labeled correctly.

Vitamin C is the world’s best natural antibiotic, antiviral, antitoxin and antihistamine. . . . orthomolecular (megavitamin) therapy concentrates on vitamin C. Let the greats be given their due. The importance of vitamin C cannot be overemphasized.

Colloidal Silver

Colloidal silver (CS) is amply discussed in Chapter 3 in its own section, so I'll summarize just a few key points here. This fluid is created when an electrical current is passed between two wires that are at least 99.99% pure silver and immersed in distilled water. Colloidal silver—or *electrolytically isolated silver* (EIS), its more chemically precise term—is not a heavy metal, despite what its detractors would like you to believe. Silver is a vital trace mineral that's naturally present in some foods, although not in enough quantities to provide significant benefits.

Quite a lot of research in respected scientific journals shows that silver not only kills most single-celled pathogens that it can touch, but it also encourages and strengthens a normal immune response without forcing it into a hyperactive state. Colloidal silver generators are sold on the Internet for about one hundred dollars, so anyone can make their own solution easily and cheaply. Some people even build their own generators from simple plans they find on the Internet.

There are many ways to use colloidal silver. To fight infections, adults might drink 2 teaspoons, 2 ounces or even 2 cups per day. For some, taking colloidal silver regularly is a way of life. A naturopath colleague in Canada uses it instead of drinking water, and as a base for all soups and beverages. His children have regularly ingested it since they were infants. None of them are vaccinated, and they have never been sick, not even with a cold.

Some water filters are impregnated with silver to kill pathogens. Medical items use silver to fight infections, such as silver-laced bandages in burn units. Socks, underwear and other clothing, all impregnated with silver threads, are marketed as fighting odors because the silver threads in them kill the bacteria that cause the odors. Establishment medicine has also combined silver with certain proteins. This creates silver compounds, which are different from electrolytically isolated, pure, unbound silver. The compounds don't destroy pathogens as effectively as CS and they can cause problems. However, they can legally be called "drugs" and thus receive patents.

Don't be surprised if your doctor is ignorant about the benefits of CS: the medical profession has done its best to denigrate the power of silver and mock the people who use it. Most people don't read medical journals, so they're unaware of decades of scientific research proving that silver heals. And researchers don't know that CS usually works better than (pharmaceutical) silver compounds.

Medical science has made such tremendous progress that there is hardly a healthy human left.

After Inoculation: Some Simple Detox Measures

If you've already been jabbed, what can you do—aside from the support already mentioned? First, the injection site has to be calmed to inactivate the foreign proteins and reduce the accompanying swelling. Place a cold pack directly on the site, for 10–20 minutes, every hour or two. Ice it for two days or until the swelling subsides. You can also use an electromedical device. It can be the electricity-producing Avazzia™ or TENS units, encircling the spot where the needle was pushed in, or the magnetic vortex-producing Magnetex®, which can be placed directly over the site. (See Appendix C for details.)

Mercury and antibiotics (which are often in vaccines) cause yeast overgrowth in the digestive tract. The antibiotics kill the beneficial gut flora, allowing *Candida albicans* to proliferate—which eats mercury for food.

Some of the friendly gut flora can be replenished with probiotics. Taking lots of colloidal silver is a great way to eliminate infectious material; but because it kills all single-celled pathogens that it touches, take probiotics at least six hours away from when you're taking the CS.

Use a sauna for at least 30 minutes a day to sweat out the toxins. There are details on a sauna therapy protocol

utilizing niacin in Chapter 3. The sooner you start sweating, the easier it will be to eliminate the poisons.

A Concise Summary of Vaccines

- ◆ Vaccines are ineffective because they don't support optimal immunity or protect people from illness.
- ◆ Vaccines are harmful because they often cause the illnesses they're purported to prevent, as well as many other serious health problems and even deaths.
- ◆ The public is brainwashed into believing that it needs vaccines because pharmaceutical companies lie about the effectiveness of vaccines and our need for them.
- ◆ Vaccines are heavily promoted by government agencies and politicians who are funded by drug manufacturers or have various financial interests in vaccines.
- ◆ Newly created laws are making it more difficult for people to refuse vaccines, which essentially allows governments to practice medicine without a license.
- ◆ It's up to each individual to be responsible for his/her own health. Parents need to become well informed so they can protect their children.

FIGHTING BIG PHARMA

In this section, I'll describe just a few of thousands of lawsuits brought by consumers against Big Pharma. Even though the final example—genetically engineered seeds made by Monsanto—might not technically be classified as a drug, the seeds act like viruses in the body. Therefore, I'll be including legal action against Monsanto as well.

Some of these lawsuits were won, but our current market economy is still heavily biased in favor of those who cheat. Dr. David Egilman, professor of medicine at Brown University in Rhode Island, once stated that ethical companies cannot compete with unethical ones because “the penalties for getting caught never approach the cost advantages of increased profit, and there rarely are criminal penalties.” The professor proposed a “reform package [that] must . . . press criminal charges against industry leaders who suppress data that results in death.”³⁸³ Unfortunately, lawsuits will be necessary until our medical and business paradigms shift, encouraging honesty, quality, and fairness in the marketplace to be the norm rather than the exception. New lawsuits will undoubtedly occur after this book is printed, so please stay informed.

Conflict-of-Interest Lawsuits

Subpoenas issued to several drug companies—among them, Bristol-Myers Squibb, Johnson and Johnson and Wyeth—were, *The British Medical Journal* online reported, “part of an investigation . . . into a pattern of financial incentives that the major drug makers have used to persuade doctors to favour their drugs.” One manufacturer, Schering-Plough, was found to have “paid doctors between \$1,000 and \$1,500 for each patient for prescribing its drug Intron A [for treating hepatitis C]. . . . Six specialists in liver disease said Schering-Plough paid ‘consulting fees’ to doctors to keep them loyal to the company’s products.”³⁸⁴

The Lawsuit Against Paxil®

In 2004, Eliot Spitzer (then New York State Attorney General)—famous for his tough stance against companies that accrue profits at the expense of public health—sued GlaxoSmithKline, the world’s second largest drug manufacturer. Among numerous infractions involving its leading antidepressant drug Paxil®, the company was accused of fraud, negligence, liability, breach of warranty, charging consumers too much—and, significantly, of suppressing studies showing that the drug caused birth defects, and made children violent and suicidal.

In October 2006, without admitting any wrongdoing for having withheld negative information about the medication’s safety and effectiveness, Glaxo agreed to pay \$63.8 million to all those involved in the class action suit. Although nearly \$64 million seems like a lot of money, the US residents who had bought Paxil® products received very little. They were entitled to a full refund—and only if they could produce records of their purchases. Those without documentation would receive fifteen dollars. If there were more plaintiffs than anticipated, the money would be divided into even smaller portions and the actual payment amounts would be less.

For some of the plaintiffs, not even a large sum could undo the damage that had been caused. Several children named in the class action lawsuit had experienced such marked personality changes after taking the drug that they committed suicide. Their parents and families were not legally entitled to any additional compensation.

As if the suicide “side” effect weren’t problematical enough, in March 2005, the FDA and the Department of Justice cited Glaxo for failing to meet FDA standards for product strength, quality, purity and safety. It was discovered that the “active” ingredients in their Paxil CR® (time-release) tablets were absent, so the tablets were taken off the market.

People taking Paxil® must wean themselves off it gradually. Abrupt withdrawal—due to either stopping the pills or taking defective pills that lack a vital ingredient—can cause shooting pains, flu-like symptoms, and suicidal tendencies. Glaxo had never warned consumers that they might be endangering themselves by using the drug. (How ironic that Paxil® can cause suicide either by its presence or abrupt absence.) Although Glaxo agreed to an independent quality control review, and to recall all of the Paxil CR® manufactured before November 2004, the company was cited later for the same infractions. One reporter comments:

It would be difficult to find a better career than employment as a GlaxoSmithKline attorney, especially if job security is a top priority. Not a year goes by when the company is not doling out millions of dollars to defend against charges involving corporate misconduct of one kind or another.

A limited review of the company’s involvement in the legal system over just the last five years reveals a clear pattern of habitual corruption. However, although Glaxo has paid billions of dollars in accumulated fines, penalties and awards to plaintiffs in civil cases, not one company official has been arrested and charged with a crime.³⁸⁵

The Lawsuit Against Vioxx®

The beginning of the 21st century brought lots of negative publicity to Merck & Co. Inc. The manufacturer's drug Vioxx®, originally approved in 1999 and prescribed for arthritis, menstrual pain and muscular pain, was causing illness and even death. The drug had earned huge profits with over 50 million prescriptions during a five-year period, so Merck fought hard to hide the truth.

One of the major whistle-blowers against Vioxx®, Dr. David Graham, had a master's degree in Public Health, had trained in internal medicine and neurology at prestigious universities, and had been Associate Director for Science and Medicine in the FDA's Office of Drug Safety. Graham's research and desire to keep the public safe had caused the removal of almost a dozen drugs from the market. Just a few were the antibiotics Omniclox® and Trovan®, the diabetes drug Rezulin®, weight loss drugs Fen-Phen and Redux®, and the over-the-counter decongestant PPA (phenylpropanolamine).

Dr. Graham willingly gave revealing testimony before the Senate Finance Committee on November 18, 2004.

Let me begin by describing what we found in our study, what others have found, and what this means for the American people. Prior to approval of Vioxx®, a study was performed by Merck. This study found nearly a 7-fold increase in heart attack risk with low dose Vioxx®. [However] the labeling at approval said nothing about heart attack risks. In November 2000, another Merck clinical trial named VIGOR found a 5-fold increase in heart attack risk with high-dose Vioxx®. . . . About 18 months after the VIGOR results were published, FDA made a labeling change about heart attack risk with high-dose Vioxx®, but did not place this in the "Warnings" section. Also, it did not ban the high-dose formulation and its use. . . .

In March of 2004, another epidemiologic study . . . found that Vioxx® increased the risk of heart attack and sudden death by 3.7 fold for high-dose and 1.5 fold for low-dose, compared to Celebrex®. . . . This report estimated that nearly 28,000 excess cases of heart attack or sudden cardiac death were caused by Vioxx®. . . . this is an extremely conservative estimate. . . . For the survivors [of the drug who were injured], their lives were changed forever. . . . Dr. Eric Topol at the Cleveland Clinic recently estimated [that] up to 160,000 cases of heart attacks and strokes [were] due to Vioxx®, in an article published in the *New England Journal of Medicine*.³⁸⁶

Double Standard

I use absolutely no drugs, not even the psychoactive drug used by 53% of Americans (caffeine). . . . I'm no supporter of marijuana or any recreational drug, but if using marijuana to feel better is a crime, then why isn't the same standard applied to prescription drugs? If you think marijuana destroys your memory, you should try statin drugs sometime. They can destroy a person's normal brain function in mere months, leaving them in a drug-induced stupor that makes potheads look downright clever. . . . In my view, we should be arresting and locking up the Big Pharma executives and corrupt FDA officials who continue to push dangerous drugs that kill 100,000 Americans each year. If you really want to protect the public from dangerous drugs, start arresting and prosecuting the truly dangerous drug dealers—the ones operating under the FDA protection racket.

—Mike Adams, 2006
naturalnews.com/019340.html

Due in part to the *New England Journal of Medicine's* disclosure that Merck had knowingly lied to make Vioxx® appear safer than it was, the company was plagued by lawsuits. Some of the lawsuits were from people who developed heart attacks, blood clots and strokes, while others were from the families of those who had died. In August 2006, a federal jury found the pharmaceutical company "negligent," having "knowingly made misrepresentations" about the drug.³⁸⁷ Merck ultimately agreed to pay \$4.85 billion to settle nearly 27,000 lawsuits, but the company did not admit causation or fault. Vioxx® was no longer manufactured.

In an interview, Dr. Graham bluntly stated that the FDA is incapable of protecting people from unsafe drugs.

The FDA . . . could have prevented much of the damage, heart attacks and deaths simply by banning the high dose Vioxx® back in mid 2000 when they knew the results of the VIGOR Study. But the FDA did nothing for almost two years.

The FDA . . . views industry as the client. They're serving industry rather than the public. . . . The FDA . . . overvalues the benefits of drugs and undervalues the risks of drugs.³⁸⁸

Not surprisingly, Graham also spoke of the tactics used by FDA personnel and other government officials to intimidate and discredit him. He continues to speak about biased or completely altered studies that deter us from making informed choices.

The Lawsuit Against Lipitor® and Other Statin Drugs

Another medical disaster occurred with an entire class of medications known as *statin* drugs. Among the most widely prescribed medicines in the United States, statin drugs are designed to reduce the amounts of serum cholesterol (fats in the blood) by inhibiting a key enzyme involved in the body's ability to synthesize cholesterol.

By now, the scenario is familiar. What pharmaceutical companies claim about safety, compared to the unwanted “side” effects that consumers report, are very different. Medical doctor and associate professor Beatrice Golomb, along with several colleagues, has collected large quantities of data on effects of statin drugs. Studying one thousand subjects in a project funded by the National Institutes of Health, the researchers found that muscle pain, weakness and tenderness are not only “common” from statins, but the “actual damage to muscle tissue can be very serious.”³⁸⁹ The muscle damage is especially insidious, another research team reported, because even though there is “clear evidence of skeletal muscle damage in statin-treated patients,” people may be “asymptomatic.”³⁹⁰ If no symptoms are felt, the person will assume that the drug is safe—until there is long-term, probably irreparable damage.

Golomb and colleagues found many negative symptoms from statin drugs. In addition to extreme fatigue, subjects often experienced “headaches, joint pains, and abdominal pain. . . . Studies have confirmed that peripheral neuropathy (tingling and numbness or burning pain) may [also] occur with statins.” Other “side” effects included:

Sleep problems, sexual function problems, fatigue, dizziness, . . . a sense of detachment, . . . swelling, shortness of breath, vision changes, changes in temperature regulation, weight change, hunger, breast enlargement, blood sugar changes, dry skin, rashes, blood pressure changes, nausea, upset stomach, bleeding, and ringing in ears or other noises.³⁹¹

Statin cause more than physical symptoms; they produce emotional and psychological changes as well. Effects on cognition, mood, and behavior manifest as depression, memory loss, and difficulties in concentration and thinking. “In some cases,” report Golomb et al., “violence, psychosis, and suicide have been reported.”³⁹² There’s debate whether all statin users suffer permanent

memory loss. Many researchers, including Golomb, have found that memory loss (and other problems) often begin when people start taking the drugs, resolve when the drugs are stopped, and return when the drugs are resumed. Unfortunately, for some people the problems linger even after the drugs are withdrawn.

What about the “side” effects (which, remember, are toxic effects) on a developing fetus whose pregnant mother is taking the prescribed statins? It’s a long list of the most unbelievably malformed soft tissue, organs, glands, nerve tissue, and bones. The malformations of statin-fed babies are so terrifying and grotesque, that

the documented dangers might seem like science fiction had researchers not corroborated the findings. The defects seem unlimited: fused ribs; short or misshapen arms and legs (in some cases, one leg is almost one-fifth shorter than the other); holes in the heart and trachea; ruptured kidneys; and stenosis (an abnormal narrowing of blood vessels) with hydrocephalus (an abnormal, excess accumulation of cerebrospinal fluid). In fact, statins are so notorious for their effects on

the development of the brain, spinal cord and protective membrane that covers the brain and spinal cord, that the medical community has given spinal and facial deformities their own category. Spina bifida (“cleft spine”), the most common neural tube defect in the United States, is frequently found in statin infants. Some babies suffer from a failure of the brains hemisphere to divide. Or they lack brain lobes entirely. Still others have malformed skull bones and facial tissue. One facial deformity is a single eye located where the root of the nose would be, with either a missing nose or a tube-shaped nose above the eye. Another facial deformity is a small flattened nose with a single nostril located below closely-set, incomplete or underdeveloped eyes. Should the baby even live (which isn’t likely), these ghastly distortions are accompanied by paralysis, urinary incontinence, bowel dysfunction, and severe retardation. Women who become pregnant while taking statin drugs subject their babies to “worse defects,” comments one medical doctor, “than were ever caused by thalidomide [another drug that caused severe birth defects, and is now banned except in certain cases].”³⁹³

One must also question whether taking statins *before* pregnancy influences a fetus. We already know that diet, both before and during pregnancy, plays a critical role in the health of a baby. Therefore, it makes sense that drugs—especially statins—would play a critical role

Drugs make a well person sick. Why would they make a sick person well?

too, because ironically, many of the birth defects occur precisely *because* the drugs are doing what they're designed to do: lower cholesterol. Despite what the medical establishment and popular press has led the public to believe, cholesterol is not a villain. As food activist Sally Fallon and fats expert Dr. Mary Enig point out:

Cholesterol is essential for the development of neural tissue, so we should expect to find that if the mother is taking a drug that inhibits cholesterol synthesis at a time when the fetus is developing, horrible developmental abnormalities will occur. Such as failure of the brain to develop in the right way, or duplication of the spinal cord.³⁹⁴

Statins also lower the levels of Coenzyme Q10, a vital nutrient. The website of the Mayo Clinic even bluntly stated (before the information was later removed):

Coenzyme Q10 (CoQ10) is produced by the human body and is necessary for the basic functioning of cells. CoQ10 levels are reported to decrease with age and to be low in patients with some chronic diseases such as heart conditions, muscular dystrophies, Parkinson's disease, cancer, diabetes, and HIV/AIDS. Some prescription drugs may also lower CoQ10 levels.³⁹⁵

Golomb and colleagues also discussed Coenzyme Q10.

There is published scientific evidence that statins lower CoQ10 levels in a dose-dependent fashion; that low levels of CoQ10 relate to muscle and brain pathology; and that restoration of CoQ10 may lead to diminution of symptoms in those with muscle or cognitive problems. We have received a number of anecdotal reports from statin users who developed muscle problems who report benefit from adequate doses (which vary from person to person) of Coenzyme Q10 supplements, which are available over the counter. There is also one small controlled study that reported benefit of CoQ10 to statin muscle symptoms. There are also controlled studies showing benefit of Coenzyme Q10 supplementation in persons who have low levels of this biochemical not necessarily related to statin use. Coenzyme Q10 should be in gelpcaps, in an oil or Vitamin E base to be absorbed.³⁹⁶

Given the horrendous deformities, and the interference with the body's normal levels of some nutrients (as well as its ability to process them), why are people taking statin drugs? The public has been convinced of a false "need." Fallon and Enig analyze Big Pharma's sales strategy.

Growth of this magnitude can only be achieved by rapidly expanding the customer base. First proposed for men deemed "at risk" for heart disease by virtue of "high" cholesterol levels, doctors now recommend statins for both men and women of all ages, diabetics and sufferers of rheumatoid arthritis. The literature even promotes statin use as a cancer prevention measure. . . .

Studies going back almost 30 years . . . [show] that the statin drugs do not provide any benefit to women who do not have already existing heart disease. [However] more healthy Americans joined the ranks of patients in July with new recommendations to lower LDL-cholesterol (the so-called "bad" cholesterol) to less than 100, [which is] *30 points lower than previously recommended*. The authors of the recommendations, which were . . . endorsed by [among others] . . . the American Heart Association and the American College of Cardiology, have made a living promoting pharmaceuticals, with most receiving honoraria from all the major drug producers, including Merck, Pfizer, Parke-Davis, AstraZeneca, Abbott, Dupont, Sankyo, Bayer and Bristol-Myers Squibb.

The challenge for the statin makers is to convince everyone "qualified" to actually take the drugs. . . . At a UK medical meeting . . . Dr. John Reckless (this is his real name!) calls for adding statins to tap water—like fluoride. (Actually some of the bestselling statins—Lipitor®, Baycol®, Crestor® and Lescor®—contain a fluoride compound.) [emphasis added]³⁹⁷

Convinced of the need to take a harmful drug, the public enriched Pfizer with 75 million prescriptions for Lipitor® in 2004. Lipitor® and another type of statin called Zocor® were the top two best-selling drugs in 2004. Figures for sales of cholesterol-lowering drugs between 2006 and 2007 were approximately \$15.5 billion per year. By 2012, sales in the US alone had climbed to almost \$29 billion per year. The statin market is so lucrative, new drugs are constantly being manufactured. It's easy to see why a drug company would do everything possible to convince people to take these toxic pharmaceuticals.

One effort designed to relieve the public's anxiety appeared as a full-page ad in the March 26, 2007 issue of *The New York Times*. The drug company clearly stated that not everyone, including people with liver problems and pregnant women, could take Lipitor®. People who experienced muscle weakness and pain they had not felt

Big Pharma Fails to Report Adverse Reactions or Deaths Due to Drugs

By law, pharmaceutical companies are supposed to report, to the FDA, adverse events (AEs) related to drugs, within fifteen days of receiving the information from consumers. Serious AEs include (but are not limited to) “death, a life-threatening adverse drug experience, inpatient hospitalization or prolongation of existing hospitalization, a persistent or significant disability/incapacity, or a congenital anomaly/birth defect.” Unexpected AEs are defined as those involving “any adverse drug experience that is not listed in the current labeling for the drug product.”³⁹⁸ The FDA uses the information received by drug companies to update drug warnings, so delays in reporting—or the lack of reporting at all—can pose extremely serious consequences for public health.

In September 2015, a review, “Drug Manufacturers’ Delayed Disclosure of Serious and Unexpected Adverse Events to the US Food and Drug Administration,” appeared in the *Journal of the American Medical Association Internal Medicine*.³⁹⁹ The authors investigated the effects of delayed submissions by manufacturers, as well as the number of disclosures that were being deliberately concealed. They found that drug manufacturers failed to disclose almost 10% of 1.6 million reports within the 15-day window. This included 120,000 cases of serious AEs—which included disability, birth defects, and life-threatening problems needing emergency care—as well as more than 40,000 deaths. Manufacturers were also likely to delay reporting serious and unexpected drug-related deaths other than AEs.

Legally, if the drug company does not maintain proper records and make timely reports, the FDA has the power (and obligation) to withdraw approval of the drug and suspend drug sales. However, according to the analysis conducted by the authors of the article, the FDA typically does not take any disciplinary action at all. The authors recommended that consumers send AE reports directly to the FDA instead of to the manufacturers, as clearly the companies cannot be trusted to follow the law.

But can the FDA?

before taking the drug were advised to tell their doctor. (The “side” effects of digestive upsets were not serious and would probably disappear, the company added.)

To me, though, the most interesting part of the ad was a statistic. For those already at risk for heart disease, Lipitor[®] was supposed to lower the probability of heart attack by 36%. This is an impressive figure. Fortunately, an asterisk led to an explanation of how those figures were determined. Not only was the 36% obtained from an unnamed number of participants who were studied for an undisclosed period of time, but the way the figure was calculated was deceptive. The reader was told that 3% of all subjects studied who took a placebo had heart attacks, compared to 2% of subjects who took the statin drug. The only way to obtain the figure of “a 36% reduction in heart attacks” is to base your calculations on the *relative* benefit: *2 out of 3 subjects taking Lipitor[®] had heart attacks, compared to 3 out of 3 not taking Lipitor[®]. Therefore, Lipitor[®] is one-third more effective.* Similar to what Dr. David Brownstein describes as a *relative* risk (see page 122), this *relative* “benefit” is a diversion. The difference in percentage points is actually insignificant. I wonder how many readers of this ad were tricked. To be fair, at least the explanation was directly below the percentage figure, and the large type was easy to read.

Another problem with the ad became public in January 2008, when the news media reported that the United States Congress was investigating Pfizer. The ad had prominently featured a photo of Robert Jarvik, inventor

of the artificial heart, above a caption stating that he took Lipitor[®] and benefited from it. Dr. Jarvik appeared to be giving medical advice. But he did not have a license to practice or prescribe medicine. According to Congress, this was misleading, and manipulated readers.

One can only hope that the dangers of statins become even more publicized, and convince people to no longer be fooled (or frightened) into taking those drugs. When the *New York Times* ad appeared, there had already been several highly publicized class action lawsuits against Pfizer, Inc. All the complaints focused on the manufacturer’s attempts to deceive the public by failing to disclose potential “side” effects of Lipitor[®] that include possibly lasting muscle damage. The symptoms did abate for some plaintiffs after the drug was stopped, but other plaintiffs stated that they continued to suffer from fatigue and tingling in the hands and feet. Significantly, a lawyer representing 19 plaintiffs in one of the lawsuits stated that Lipitor’s[®] effectiveness in lowering cholesterol levels was not in dispute. He wrote:

Rather, these lawsuits charge that Pfizer failed to adequately warn both doctors and consumers of the drug’s more serious and sometimes permanent health risks—risks that Pfizer was well aware of in its own clinical studies of statin usage. Pfizer has apparently engaged in a campaign of misinformation, designed to downplay and cover up Lipitor’s[®] more serious and irreversible side effects, and is willing to promote the drug at any cost.⁴⁰⁰

Sadly, some of the court papers mentioned that although Lipitor® lowers blood cholesterol, there is no proof that the drug reduces the risk of heart disease in women or the elderly. In fact, the very people who are likely to take cholesterol-lowering drugs are those who are most at risk of damage from the drugs. In 2002, a physician with 17 years of medical practice wrote:

All patients taking statins become depleted in Coenzyme Q10 (CoQ10) eventually. Those patients who start with a relatively low CoQ10 level (the elderly and patients with heart failure) begin to manifest signs/symptoms of CoQ10 deficiency relatively rapidly, in 6 to 12 months. Younger, healthier people whose only “illness” is the non-illness “hypercholesterolemia” can tolerate statins for several years before getting into trouble with fatigue, muscle weakness and soreness . . . and most ominously, heart failure.⁴⁰¹

Lipitor® is only one of many statin drugs whose manufacturer has been sued. An Internet search I made at one time, using the keywords “statin,” “Bayer,” “Lipobay®” and “Baycol®,” yielded a wealth of reading material—and reports of settlements for over 3,000 lawsuits.

In the UK, some statin drugs can be bought without a prescription.

Lawsuits Against Tylenol®

Pain is big business. With so many Americans suffering from chronic inflammation (frequently caused by toxic chemicals and improper diet), it’s often perceived as easier to pop a pill to numb the pain than to make long-lasting, but more difficult and time-consuming changes. It’s for this market that painkillers were created.

After the first mass-marketed painkiller, aspirin, proved too weak to numb pain, acetaminophen was created. Sold as Tylenol®, Atasol®, Anacin-3®, Panadol®, and Excedrin® (which also contains aspirin and caffeine), acetaminophen is the most popular medicine in the US. But its negative effects are many and severe: significantly increased risk of high blood pressure in all age groups, fatal kidney failure, and liver failure (it depletes glutathione, which ordinarily protects the liver from poisons). In fact, a 2005 article, “Acetaminophen-induced acute liver failure: results of a United States multicenter, prospective study,” showed that acetaminophen caused 42% of all acute liver failure cases between 1998 and 2003.⁴⁰² Many of these people died.

Liver failure from this drug is so widespread that as of June 2013, 187 lawsuits have been filed against the manufacturers of Tylenol®, McNeil-PPC, and its parent company, Johnson & Johnson. Other suits are pending.

Lawsuits Involving Monsanto

Monsanto, sometimes called “Monsatan” by its critics, is responsible for altering the world’s food supply in horrific ways. In 2018 Monsanto merged with Bayer, with its name now eliminated by the merger. After briefly reviewing Monsanto’s history, we can guess why this was done.

Founded in 1901 by a pharmaceutical company veteran, Monsanto’s first product was saccharin, a carcinogenic artificial sweetener. In 1917, the US government sued Monsanto over the sweetener’s safety, but Monsanto won after a few years in court. By the 1920s, the company had expanded its product line to include industrial chemicals as well as drugs. Along with aspirin, the company manufactured polychlorinated biphenyls (PCBs), used as a lubricant and put into waterproof coatings. Widely known as the oil that would not burn, PCBs are highly toxic: they cause reproductive disorders, cancers, and immune system malfunction. At the time that Monsanto was manufacturing PCBs, it routinely discharged tons of the chemical into creeks and landfills, knowing of the dangers. The highest rate of fetal deaths in the country were recorded at the location of the primary manufacturing plant, in East St. Louis, Missouri, US. Today, fifty years after PCBs were banned, they are still found in human and animal blood all over the world.

In the 1950s, Monsanto created a toxic plastic that was used to create several buildings at Tomorrowland, a Disney theme park. When the time came to dismantle the buildings, the glass-fiber, reinforced polyester material could not be destroyed with wrecking balls, jackhammers, torches, or chain saws. The buildings could be removed only with choker cables, which, bit by bit, squeezed off pieces that were then hauled away in trucks.

Monsanto produced the pesticide DDT (now banned). In the 1960s, in partnership with Dow Chemical, Monsanto created a defoliant herbicide called Agent Orange. Sprayed during the Vietnam war to strip the leaves from all vegetation—presumably used to make it difficult for enemy soldiers to hide in the jungle—it also fell on American troops. The dioxin in Agent Orange has been responsible for millions of deaths, birth defects and continued illness, in both Vietnamese and Americans. Accused of knowing dioxin’s effects when it sold the chemical to the government, Monsanto insisted that its own research had proven the herbicide safe. But at a 2002 trial, a company memo was released: “The evidence proving the persistence of these compounds and their universal presence as residues in the environment is beyond question . . . the public and legal pressures to eliminate them to prevent global contamination are inevitable. . . . Where do we go from here? The alternatives: go out of

business; sell the hell out of them as long as we can and do nothing else; try to stay in business; have alternative products.”⁴⁰³

In 1997, Monsanto sold its chemical plants to focus on “biotechnology.” Its two branches of business were Agricultural Productivity, and Seeds and Genomics. The Agricultural Productivity department included Roundup® herbicide and other chemicals used in agriculture, along with the Animal Agriculture business. The Seeds and Genomics department consisted of seed companies and plant genetics technology. “In reality of course,” states the article, “Monsanto’s Dark History: 1901–2011,” “these two segments are inseparable, since the agri-chemicals are becoming increasingly dependent on the seeds segment for sales.”⁴⁰⁴ Monsanto continued to develop, promote and sell more types and amounts of its genetically engineered seeds so it could sell more glyphosate, otherwise known as Roundup®. (See Chapter 3, **Food**, for more details on genetically engineered or GE seeds made with GMOs, an acronym for “genetically modified organisms.”)

The World Health Organization defines GMO “foods” as “derived from organisms whose genetic material (DNA) has been modified in a way that does not occur naturally, e.g. through the introduction of a gene from a different organism.”⁴⁰⁵ Here are some highlights of GMO effects:

- ◆ Laboratory experiments with animals show that GMOs cause allergies, seizures, brain lesions, cancers, and reproductive disorders (sterility, miscarriages, birth defects, and 50% infant mortality rates). Offspring of animals who eat GE plants are smaller and sterile. GE soy has been found to deplete glutathione from the body, and when fed to hamsters, causes fur to grow inside their mouths. GE crops (and the glyphosate used on them) have killed huge numbers of several species of beneficial insects, as well as over one-half of

the world’s bee population where GMOs are planted. The beneficial flora living in the guts of humans (and animals) adopt the DNA of the GE feed. Glyphosate creates the neurotoxin formaldehyde when it degrades; causes fatal kidney damage (due to its ability to attract heavy metals); and (as shown by Dr. Stephanie Seneff’s research) damages the pineal gland, leading to autism.

- ◆ Scientists who have reviewed data from Monsanto’s own studies “have proven that genetically engineered foods are neither sufficiently healthy or proper to be commercialized.”⁴⁰⁶ Moreover, WHO, as well as Massachusetts Institute of Technology scientists, have publicly, unequivocally stated that glyphosate causes genetic damage that can lead to many forms of cancer.
- ◆ “Super weeds”—that is, weeds resistant to glyphosate—have emerged. This means that more Roundup® “needs” to be used on crops, and that the humans and animals who eat these plants are ingesting more Roundup® with their food.
- ◆ When given a choice between GMO and non-GMO feed, animals will refuse to eat GMO feed.
- ◆ Per acre, crops grown from GE seeds are more meager than even conventionally grown (and sprayed) crops.
- ◆ Some of the seeds produced by Monsanto are called “Terminator Seeds.” They produce sterile crops, so that if farmers saved the seeds from last year’s GE harvest (which a Monsanto contract they’re forced to sign makes illegal), they’re unable to grow new plants from those seeds. There are very few plants in nature that work like this; most are able to be pollinated.
- ◆ GE seeds have blown into the fields of farmers who never wanted them and never even planted them. However, this hasn’t stopped Monsanto from suing hundreds of farmers for patent infringement. Monsanto representatives have been known to sneak into the non-GMO farmers’ fields during the night, and take samples of the plants to determine if any of them were genetically engineered. Many farmers have committed suicide as a result of losing their livelihoods.
- ◆ The import, distribution and utilization of GMOs, entirely or partly, are banned in most countries outside the United States (although some other governments and their agencies, such as The Royal Society in the UK, have also aligned themselves with Monsanto). Several states in the US have passed laws prohibiting the presence of GMOs in any foods, but the US federal government has been working hard to overturn states’ rights over the “rights” of Monsanto to poison humans, animals, and the environment.

Probably the greatest threat from genetically altered crops is the insertion of modified virus and insect virus genes into crops. . . . genetic recombination will create highly virulent new viruses from such constructions. The widely used cauliflower mosaic virus (present in the GM soy and maize currently on supermarket shelves in the UK) is a potentially dangerous gene. It is very similar to the Hepatitis B virus and related to HIV. Modified viruses could cause famine by destroying crops or cause human and animal diseases of tremendous power.

- ◆ Monsanto has fought hard in the US courts to prevent products containing GMOs from being labeled—even though surveys show that over 90% of consumers want this labeling, believing that they have a right to know what’s in their food. The US government protects GMOs, no matter how much devastation they cause.
- ◆ Monsanto paid university professors and people in the sciences (such as \$25,000 to Dr. Kevin Folta, at the University of Florida) to say that GMOs are harmless and even beneficial. Articles exposing collusion between Monsanto and corporate groups operating under the guise of academia, as well as a photograph of Monsanto’s letter to Folta, are at GMO.news.

Attorney Steven M. Druker’s extensively documented 2015 book, *Altered Genes, Twisted Truth*, describes a 1996 lawsuit initiated by Druker and others against the FDA. As part of the disclosure process, the agency was legally forced to provide over 44,000 pages of reports, messages, and memoranda pertaining to GE foods. The FDA’s own files showed that even while knowing the risks of GE foods—for more than 30 years—the agency became an ally of the biotechnology industry and actively promoted its products. “I had compiled extensive evidence,” Druker writes, “of an enormous ongoing fraud.”

The FDA had ushered these controversial products onto the market by evading the standards of science, deliberately breaking the law, and seriously misrepresenting the facts . . . people were being regularly (and unknowingly) subjected to novel foods that were abnormally risky in the eyes of the agency’s own scientists.

This fraud has been the pivotal event in the commercialization of genetically engineered foods. Not only did it enable their marketing and acceptance in the United States, it set the stage for their sale in numerous other nations as well. If the FDA had not evaded the food safety laws, every GE food would have been required to undergo rigorous long-term testing; and if it had not covered up the concerns of its [own] scientists and falsely reported the facts, the public would have been alerted to the risks. Consequently, the introduction of GE foods would at minimum have been delayed many years—and most likely would never have happened.⁴⁰⁷

Monsanto has remained silent about Druker’s book, perhaps hoping that the public has simply become too ill to care that it was defrauded. “Or,” writes one investigative reporter, “perhaps the company is just too preoccupied

Seed Companies Not Owned by Monsanto (or as of 2018, the merged Monsanto-Bayer)

The following North American companies sell seeds that are not genetically engineered (GMO). Most of these companies do not purchase from Monsanto, from Monsanto-owned Seminis, or from Bayer (which merged with Monsanto and now conceals the Monsanto name). However, companies are being bought and sold all the time, so verify that these companies are still independent before you purchase.

See seedsave.org for smaller seed companies started by members of Seed School, and for information on seed libraries and how to save your own seeds.

In 2000, the FDA won the lawsuit instituted by Druker. However, at least one lawsuit has had a just outcome. In California, as part of his school groundskeeper job, 46-year-old Dewayne Johnson had been required to regularly handle Roundup® weed killer. Even though he wisely used protection, he still contracted non-Hodgkin’s lymphoma. So in August 2018, a California jury ordered Monsanto to pay Mr. Johnson \$289 million for failing to properly label the product and acting with malice and oppression due to its reckless disregard for human life. Of course, Monsanto is planning to appeal.

Monsanto’s sales offices, factories and research centers (in over one hundred countries) have multiplied since its merger with the Bayer corporation. Bayer also has a dark history. Known as I.G. Farben during World War II, Bayer used Jewish slave laborers, manufactured the poison used in gas chambers to kill concentration camp prisoners, and its scientists (later convicted for war crimes) experimented on prisoners. Today, Bayer sells over 90% of the world’s genetically modified seeds and most of its pesticides and herbicides. The corporation is also working hard to receive patents for the DNA of both animals and humans.

Granting Legal Immunity

The FDA has protected drug companies so rigorously that ethical US government officials finally began to notice. So did the press. *New York Times* reporter Gardiner Harris, who often writes about medical politics, wrote in 2004:

The chairman of a House committee angrily accused the Food and Drug Administration on Thursday of withholding documents on the effects of antidepressants on children. Holding a copy of an e-mail message from an agency official instructing others in the agency not to unearth documents, . . . Joe L. Barton . . . said it demonstrated that the agency was deliberately defying the panel. He threatened to ask police officers to go to the agency’s offices to retrieve the records.

“The FDA’s lack of cooperation with the committee in obtaining relevant and responsive

information in a timely fashion on a matter that involves the safety of our children leaves me wondering whether this is sheer ineptitude or something far worse,” Mr. Barton said. . . .

Seven top executives from drug giants like Pfizer, Wyeth and Glaxo-SmithKline were sharply questioned about why the companies had collectively failed to publish or publicize results of studies showing that their drugs had not proved effective in treating depressed teenagers and children.⁴⁰⁹

As one might expect, with the rapid escalation of such negative publicity, the FDA began to defend itself. In July 2006, a *New York Times* headline read, “FDA Rules Will Regulate Experts’ Ties to Drug Makers.” The agency apparently stated that new rules would make it:

impossible for experts who get money from drug makers’ marketing departments to serve on advisory committees. That would exclude, for instance, anyone who was paid by the marketing departments to promote drugs. . . . [However] Agency officials said they had no intention of excluding all advisers with ties to drug makers.⁴¹⁰

In other words, the FDA had no intention at all to behave ethically, as its continued behavior has proven. For now at least, consumers of pharmaceuticals are unprotected. Even in cases of serious damage or death, as long as drugs or medical devices have been approved by the FDA, pharmaceutical companies have no legal liability, even if:

- ◆ The item’s label is insufficient or deceptive.
- ◆ Approval of the drug/device has been based on incomplete testing.
- ◆ The company had misled the FDA into approving the product by submitting falsified reports.
- ◆ The FDA received reports of damage or death associated with the products.
- ◆ The FDA failed to warn of the product’s dangers after receiving complaints.

Big Pharma’s glaring misdeeds are becoming more visible than ever. Before reaching for the medicine cabinet to pop a pill, or seeing your doctor for an injection, consider how many drugs you really want to be taking—and ultimately, if the risks are worth it, particularly when there are safe and effective alternatives. The rest of this book discusses our options; but for now, let’s briefly examine some more problems.

DRUGS WHERE THEY'RE NOT INTENDED

It's bad enough that most drugs don't work and have undesirable "side" effects. But at least those of us who choose not to medicate ourselves don't have to—right? Not exactly.

Antibiotics in Food

Many people who are afflicted with an infection find it comforting to take antibiotics. According to Null and colleagues, in the United States between 3 and 5 million pounds of antibiotics are used on humans every year. "With a population of 284 million, . . . this amount is enough to give every man, woman and child 10 teaspoons of pure antibiotics per year."⁴¹¹ The misuse of antibiotics is rampant. Almost half of the people with upper respiratory tract infections receive antibiotics from their doctor, even though the CDC cautions that 90% of these infections (including children's ear infections) are viral. Antibiotics cannot destroy viruses.

Alas, humans are not the only ones given antibiotics. In 2003, Null et al. reported that about 25 million pounds a year were used on animals raised for food—and that of this amount, over 23 million pounds were given not to treat disease, but to try to prevent it (as well as to stimulate growth). By 2009, according to the FDA, the number of pounds of antibiotics used on animals raised for food had climbed to 29 million pounds. Put another way, farm animals get 80% of all antibiotics sold in the US.⁴¹²

The need for disease prevention is due to the unnatural and stressful conditions under which factory farmed animals are forced to live. These animals are confined in crowded quarters, with a deficit of sunshine and fresh air, and forced to consume food they were never meant to eat. This is discussed more in Chapter 3.

Overuse of antibiotics, Null and colleagues reported:

[results] in foodborne infections resistant to antibiotics. Salmonella is found in 20% of ground meat but constant exposure of cattle to antibiotics has made 84% of salmonella resistant to at least one anti-salmonella antibiotic. Diseased animal food accounts for 80% of salmonellosis in humans, or 1.4 million cases a year. . . . Approximately 20% of chickens are contaminated

with *Campylobacter jejuni* causing 2.4 million human cases of illness annually. Fifty-four percent of these organisms are resistant to at least one anti-*Campylobacter* antimicrobial.⁴¹³

We've known for two decades ago that the antibiotics people are forced to eat and drink have conferred antibiotic resistance in germs. In Scandinavia and other parts of the world, it has been found that decreasing the amount of antibiotics given to animals has little effect on food production costs. However, the US has not shown the same incentive in minimizing or eliminating this practice.

Excess antibiotic use has even affected plants. Both organic and conventional crops that are grown with manure from antibiotic-fed animals are taking in the drugs through their roots. Thus, whoever eats the plants takes in unwanted drugs as well.

Drugs in Drinking Water

People who are careful to limit their intake of pharmaceuticals, or who avoid taking them entirely, may still unwillingly ingest all kinds of drugs every time they take a sip of water. Detectable levels of drugs exist

in virtually every body of water today, worldwide. According to the Environmental Protection Agency, whether the river, lake, creek, aquifer or groundwater is urban or rural, obviously dirty or seemingly pristine, it contains drugs. Our water also contains drug metabolites, which are byproducts, produced by the body, of the primary ingested chemicals.

How do drugs get into our water supply? The metabolites are excreted in urine. Hospital personnel flush expired and unused medications down the toilet. Consumers are

sometimes advised to do the same. Drug companies pump waste from the manufacture of pharmaceuticals into nearby, convenient water bodies. These chemicals are not removed by most municipal filtering systems, which use even more chemicals to treat the water rather than the much safer, and very effective methods using carbon filtering, ultraviolet light, and ozone.

"An aging population and our growing addiction to pharmaceuticals may have disastrous consequences for our water supply," writes Elizabeth Royte in "How Prescription Drugs Are Poisoning Our Waters." She describes how massive amounts of drugs move through the systems of the elderly into the water system:

Since [US President] Obama appointed his crony Margaret Hamburg as FDA Commissioner in 2009, the FDA has collected over \$2.3 billion [in donations] from major drug companies including Bristol-Myers, Merck, Johnson & Johnson, Pfizer, GlaxoSmithKline, and Eli Lilly.

Director, The Health Sciences Institute
(undated quote)

Heritage Village [is] a sprawling retirement community in western Connecticut. . . . [Its approximately 4,000 residents] take an average of six drugs a day. And that's a healthy population.

In a convalescent home a few miles away, Patricia Reilly, age 88, wheels herself each morning toward a low shelf. With a glass of water and small cups of applesauce at the ready, she prepares to take her morning medicines: nine different types that treat heart disease, acid reflux, renal stones, a chronic urinary tract infection, chronic constipation, migraine headaches, depression, allergic rhinitis, degenerative arthritis, and intermittent vertigo. The 120 residents of River Glen Health Care Center, where the average age is 90, take an average of eight drugs a day; the most common among them target high cholesterol, high blood pressure, depression, and diabetes. Once swallowed, . . . [the medicines'] biological activity won't stop once they leave her body.

When residents of Heritage Village and two other nearby retirement communities flush their toilets, wastewater laced with traces of prescription drugs rushes through a series of pipes into the Heritage Village treatment plant. . . . Through a process of settling and aeration, the Heritage Village plant separates liquids from solids, treats the liquid portion with disinfectant, and then discharges this effluent into a mini-creek . . . The effect of those drugs on the environment, and possibly on those who drink water pumped from those streams, is only beginning to be understood.⁴¹⁴

The effects of environmental medications are extensively documented. These examples are summarized from Royte's article.

- ◆ A Baylor University researcher found tiny amounts of Prozac® in liver and brain tissue of channel catfish and in black crappie captured in a creek near Dallas, which receives almost all of its flow from a wastewater treatment plant.
- ◆ A University of Georgia scientist found that tadpoles exposed to Prozac® morphed into undersize frogs, vulnerable to predation and environmental stress.
- ◆ The EPA reports that antidepressants can have a profound effect on spawning behaviors in shellfish, and that calcium-channel blockers (used to relieve chest pain and hypertension) can dramatically inhibit sperm activity in some aquatic organisms.

- ◆ Even at extremely low levels, ibuprofen, steroids, and antifibrotics (drugs that help reduce the development of scar tissue) block fin regeneration in fish.
- ◆ According to a report by the Scientific Committee on Problems of the Environment and the International Union of Pure and Applied Chemistry, more than 200 water and land species have suffered adverse endocrine disruption due to medicinal and synthetic estrogens.

Fish, frogs, and lab rats aren't the only life forms that are negatively affected by drugs. People are being affected too—on behavioral, cognitive, immune, neurological, and reproductive levels. Mercury, produced from the burning of coal and hazardous waste, the manufacture of chlorine and cement, and the refining of metal, is in our water supply as well as in vaccines and dental amalgams. Another long-term danger is synthetic estrogen in the environment, found in medicines and in most plastic containers that store foods. Not only does synthetic estrogen cause lowered sperm counts in males, but it feminizes male infants and children and even adult men. Males may suffer not only enlarged breasts, but also psychological damage. High levels of synthetic estrogens are flooding male (as well as female) fetuses, and this affects brain structure and function. Some practitioners are beginning to wonder if this hormone mismatch is partly behind the growing trend toward transgenderism, the feeling that one is born into the wrong-sex body.

Generally, a health risk assessment is based on the analysis of one chemical at a time. But this approach doesn't accurately reflect exposure to many chemical compounds at once. A 2002 US Geological Survey found traces of 82 different contaminants—including drugs, fertilizers, and flame retardants—in surface waters across the United States. The drugs included antibiotics, antidepressants, hormones, blood pressure pills, and painkillers.

Toxicological expertise now exists to assess the effects of many chemicals combined, which is how they are found in our environment. Whereas a single chemical might not have produced an effect, it takes lesser amounts, and lower levels of exposure, to produce symptoms when someone is exposed to chemical stew.

"I'm worried for fish populations, and I'm worried for human populations," says environmental endocrinologist David Norris. "The levels found in Boulder Creek [a body of water he studied] are low in absolute terms, but they aren't low on the biological level. You could have six chemicals below the no-effect level, but all together they are above the no-effect level."⁴¹⁵ This is why our symptoms from chemical cocktails are considered iatrogenic disease by Null and his colleagues.

ELECTRONIC MEDIA AS A DRUG

Sonograms

It must be hard being a child or teenager today, especially in a highly industrialized nation like the United States. Here, even young children are impacted by national debt and poverty (one in forty-five children is homeless). Wars and civil unrest have regularly become front page headlines, causing many children to grow up with anxiety about their uncertain futures. The average person's diet is laden with sugars, artificial chemicals and dyes that cause hyperactivity, cancers and other health problems (discussed in depth in Chapter 3). Many people are too poor to buy foods that are organic, or which at the very least don't contain GMOs. Plus, meaningful education is often elusive. People experience the most intense growth spurt of their lives when they're children and they need to discharge their boundless energy in physical ways. Yet instead, they must endure hours of classes that are usually boring and irrelevant. Unable to tolerate what no adult would willingly undergo—sitting still in what amounts to an indoor prison—children are labeled “ill” and forced to take mind-altering drugs. It's no wonder that electronic media has provided such a respite from the world and its ills. Never in human history have so many children grown up wired and plugged in, even before birth.

The first direct exposure to electronics occurs in the womb. In technologically advanced nations, pregnant women usually receive one or more *ultrasound* tests, each of which produces a picture called a *sonogram*. Ultrasound uses very (“ultra”) high frequency sound waves above the range of human hearing, ranging from 1 or 2 MHz (megahertz) to 18 MHz. (The lower the frequency, the more the signal penetrates. The higher the frequency, the less the signal penetrates.) Ultrasound machines generate sound waves in pulses of less than one ten thousandth of a second. Pulses are utilized because a continuous sound wave can generate too much heat in the tissue.

There are many applications for ultrasound. Depending on what frequency range is being employed, ultrasound can promote growth (such as regenerate bone) or destroy material (such as break apart kidney stones or gallstones). Ultrasound can also heat tissue to the point of causing damage. It can induce neurons to misfire, and poke holes in cell membranes.

Using common sense, why would anyone think that intruding upon the continuous, seamless development of the fetus, which has for millions of years completed its work without assistance, be without consequences?

—Caroline Rodgers

“Questions About Prenatal Ultrasound and the Alarming Increase in Autism”
Midwifery Today, Winter 2006

The application of ultrasound that's pertinent to our discussion is its ability to create an image of an object or structure inside the body. That image can be the stomach, liver, heart, gallbladder, a muscle—or a developing baby. The sound bounces off an object, and produces a picture based on the object's density and shape.

Originally designed for industrial use to detect flaws in metal, ultrasound for medical purposes was first used by a Scottish obstetrician in 1955. He initially experimented on various tumors, which he found produced different echoes. Soon after, ultrasound was aimed not only at women's abdominal tumors, but also on their pregnant bellies. Justified as useful for detecting abnormal or insufficient growth in developing fetuses, the test became standard (and big business) in industrialized countries. However, no scientifically valid tests for safety were conducted. Just as with X-rays—which pregnant women were receiving for 50 years (to assess fetal size) before it was discovered that the X-rays were causing birth defects—it was simply *assumed* that ultrasound was safe.

But now, some researchers are finally acknowledging the complexities of how ultrasound actually works and the negative consequences of using it. The question is whether doctors and expectant parents are listening.

The physical effects of ultrasound include both its pressure on the water within and surrounding a given cell, and through the creation, oscillation (spinning), and implosion of bubbles in that same liquid. The latter is referred to as “cavitation” or the creation of a gaseous cavity within the liquid. Cavitation and noncavitation effects together can poke transient holes in cells, activate certain molecular pathways within those cells, cause temperature increases when the bubble violently implodes, promote the creation of free radicals (oxidation) when that gas escapes into the surrounding medium which can subsequently damage or even kill a cell, can cause general disarray within the cell, and at certain intensities may even promote mutations of DNA.

Most of the deadly effects on cells are generally not seen at diagnostic intensity levels. However, there is still the potential that ultrasound is altering how normal cells develop and behave. That is, it doesn't kill them, but it may very well change them.⁴¹⁶

Is the fetal reaction to ultrasound considered important? No, even though developing infants instinctively tend to move away from the stream of high-frequency sound waves (which should be a clue that the stimulus is harmful.) In 2004, the FDA warned that “ultrasound is a form of energy, and even at low levels, laboratory studies have shown it can produce physical effect in tissue, such as jarring vibrations and a rise in temperature.”⁴¹⁷ (Author Caroline Rodgers quotes this directly from an FDA web page she reported accessing in 2004. Yet, an Internet search I conducted eleven years later produced a version of the original page that did not include this passage.)

“Fetuses can hear ultrasound examinations” is the self-explanatory title of a *New Scientist* article published in 2001. Researchers inserted a tiny hydrophone inside a woman’s uterus while she was receiving an ultrasound. “Sure enough, they picked up a hum . . . similar to the highest notes on a piano. . . . When the ultrasound probe pointed right at the hydrophone, it registered 100 decibels, as loud as a subway train coming into a station. ‘It’s fairly loud if the probe is aimed right at the ear of the fetus,’ says [a research doctor, James] Greenleaf.”⁴¹⁸

Ultrasound can cause dyslexia, epilepsy, learning difficulties, and delayed speech in the infants. Women exposed to ultrasound have an increase in spontaneous abortions and stillbirths. In “Randomized prospective trial comparing ultrasonography and pelvic examination for preterm labor surveillance,” the authors write:

The overall rate of prematurity was 18%. Preterm labor was more frequent with ultrasonographic evaluation (52%) than with pelvic examination (25%) . . . In this prospective randomized study of patients at risk for preterm birth, patients under surveillance by ultrasonographic assessment of the cervix did not fare better than those assigned to bimanual examination.⁴¹⁹

Sonograms harm more than just the fetus exposed to the technology. In “Ultrasound—The Mythology of a Safe and Painless Technology,” presented to the Royal Society of Medicine in the UK in 1995, the speaker stated: “the subtle effects of ultrasound may not emerge until the next generation. No one mentions to women that when they are scanned their baby is already carrying the next

generation’s eggs, so when she becomes pregnant those eggs have already had x numbers of ultrasound scans.”⁴²⁰ The dangers of ultrasound technologies have been known for decades, but the medical establishment has chosen profits and the mechanization of medicine over people’s health. Ultrasound testing isn’t even very accurate. It produces a significant number of “false positives” for defects, making it a highly imperfect diagnostic tool.

Thus sonograms hurt the very baby that expectant parents are so eager to welcome into their lives. Ironically, a large number of these parents request a sonogram not to discover (and then possibly treat) a medical condition, but to have a “fun” photo—or even better, a series of photos—to document the growth of their child! This powerful, hazardous equipment has lost all pretense of having a medical purpose and is instead treated as entertainment: intrauterine photography. Note that the FDA’s current, restrained website page still cautions parents that to order a sonogram merely to possess a “keepsake” photo is a misuse of the medical testing (even though, the FDA still insists, the procedure is not dangerous).

Increasing concern has arisen regarding the fetal safety of widely used diagnostic ultrasound in obstetrics. Animal studies have been reported to reveal delayed neuromuscular development, altered emotional behavior, EEG (brain wave changes, anomalies, and decreased survival. Genetic alterations have also been demonstrated in *in vitro* systems.

Effects of Electronic Distractions

In our media-oriented, entertainment-happy culture, ultrasounds condition us to invite further bombardment from all kinds of electronic gadgets. Children clamor for (and receive) iPhones®, iPods®, video games, tablets, and computers. With these amazing devices, anyone can access information, diversion, amusement, escape, and people all over the world. While these activities can be enjoyable, the electronics are also playing a decisive role in harnessing people’s energy and even directing their minds. When used in excess, especially by children and teenagers, these devices can stunt growth as palpably as a poor diet.

Old style computers, TVs, and video games didn’t have flat screens. Bulky, heavy and rounded, the monitors utilized cathode ray tube technology at relatively high voltages, emitting a wide spectrum of noxious radiation including extremely low frequencies, “soft” X-rays, and radio frequencies existing within certain dangerous bands on the electromagnetic spectrum. While the newer flat screen technologies don’t emit these harmful wavelengths, they do cause damage.

Impaired Cognitive Abilities

Constant bombardment by electronic media can impair intelligence. I'm not just talking about content (although that can certainly decrease creative, original, and rational thinking!). I'm referring to visual bombardment, which affects the brain in some unexpected ways.

The visual cortex of the brain occupies a huge amount of space, compared to other areas. About 50% of the brain's nerve fibers are directly or indirectly linked to vision; and when the eyes are open, two-thirds of the brain's electrical activity is devoted to vision. Neurodevelopmental optometrist Merrill D. Bowan writes, "Vision is a bully: it tries to persuade our brain that what it is sensing through vision is the only reality, whether its perception is accurate or not." As an example, he cites what happens when the eyes look through a special pair of optical prisms. They "not only change the apparent shape of a vertical edge, but also how it feels"—in other words, one's *kinesthetic* sense, or perception of the position, weight, and movement of the body in space. One's kinesthetic sense doesn't exist independently of vision. When the eyes look through these prisms,

the edge will now actually feel bowed to the vast majority of people. Closing the eyes will extinguish the feeling of bowedness, and opening them restores it once again. Vision is integrated with the other senses and dominates them so fully that the brain has to almost stop, figuratively, and weigh the visual input with the proprioceptive [body sensing], the auditory and to a lesser extent, the gustatory and the olfactory data to be assured that the perceptions we're processing is accurate. As kids might say these days, "Vision Rules!"⁴²¹

Vision plays such a huge role in how we respond with our other senses, that learning—especially for infants, young children and teens—should ideally integrate the visual, auditory, and kinesthetic (tactile and movement) senses. Each sense exponentially adds to the enrichment of the others, which is why the best teaching environments for babies and children are multifaceted. When more than one area of the brain is used at the same time, neural pathway connections are created between these areas, which makes us smarter.

The complexity of the brain helps explain why language (to use one example) is based not only on auditory input, but also on vision, plus the ability to mentally process and interpret that visual input. In fact, the brain is so complex that even brainwaves are intimately connected to vision—which by definition includes eye movements.

The number and type of eye movements required to take in an entire, compressed scene on a computer or TV screen are vastly fewer—and different—from movements the eye would make if it were scanning the natural environment. Even if the TV is a huge widescreen model, the screen remains at a fixed distance. In comparison, for someone who's outside, the range of eye movements varies tremendously. The eye is constantly shifting: side to side, up and down, and from close to far away and back again. By definition, one cannot obtain this depth and breadth of field when viewing a stationary screen.

Simply put, *abnormal eye movements create abnormal brain wave patterns*. This is what prompted one academic to write: "Since the brain is organizing during the first years of life and since human beings evolved responding to three-dimensional stimuli, I wondered if exposing toddlers to lots of colorful two-dimensional stimulation could be harmful to brain development."⁴²²

A surprisingly large number of studies have indeed confirmed that "two-dimensional stimulation"—in this case, television—can harm the brain's development. One of the best studies, published in the April 2004 issue of *Pediatrics*, had the self-evident title of "Early Television Exposure and Subsequent Attentional Problems in Children." This was an important study because it was longitudinal—in other words, there was long-term follow-up. Researchers monitored the progress of 1,278 one-year-olds and 1,345 three-year-olds to the time they reached 7 years of age. At the end, their status was tallied. A total of 10% of all the children suffered from "attentional problems."⁴²³

A report on the same research appeared the following year in another publication, *Journal of the American Medical Association: Pediatrics*, titled "Children's Television Viewing and Cognitive Outcomes: A Longitudinal Analysis of National Data." The text of this study, which appears online in its entirety, is worth excerpting. "A large number of studies have reported deleterious effects of children's television viewing on outcomes such as obesity, inactivity, attentional problems, aggression, and sleep patterns." After statistically adjusting for "parental cognitive stimulation throughout early childhood, maternal education, and IQ," the authors concluded that "each hour of average daily television viewing before age 3 years was associated with deleterious effects" on several tests that measure reading recognition, reading comprehension, and intelligence.⁴²⁴

The authors were very careful to distinguish between educational and non-educational television programs. "Children who watch episodes of educational television, such as *Sesame Street*, *Mr. Rogers' Neighborhood*, and *Blue's Clues*, demonstrate improvements in educational domains

The Brain Changes in Response to the Environment

In some experiments, researchers studying the effects of enriched environments on rat brains found that laboratory-raised rats (in cages) that were exposed to interesting social interactions and varied activities, developed brains that were heavier and denser than the brains of their unenriched counterparts. In other experiments, rats taught how to navigate mazes yielded similarly more intricate brains than their unschooled counterparts that were not exposed to multifaceted environments. But wild rats had the heaviest, and most complex, brains of all. The types of socialization and activities that the wild rats enjoyed affected the density of nerve cells in many regions of their brains, including the corpus callosum (a rope-like structure that separates the right and left hemispheres), and in the cortex (learning center). These changes occurred regardless of how old the rats were.

Simply put, the brain can grow neurons, and develop new pathways of connections, in response to beneficial stimuli and learning. In "Response of the Brain to Enrichment," neuroanatomist Marian C. Diamond states: "Before 1960, the brain was considered by scientists to be immutable, subject only to genetic control. . . . By 1964, two research laboratories proved that the morphology and chemistry of the brain could be experientially altered. . . . Since then, the capacity of the brain to respond to environmental input, specifically 'enrichment,' has become an accepted fact among neuroscientists, educators and others. . . . It is essential to note that enrichment effects on the brain have consequences on behavior."⁴²⁵

Neurodevelopmental optometrist Merrill D. Bowan writes: "Input modifies brain structure, which further modifies the response. . . . The brain has been treated as though it alone impacts behavior, but the exciting new direction in neuropsychological research is that behavior has durable impact on the brain."⁴²⁶

Some scientists, but not all, have known about the "plasticity" of the brain for decades. Now it's time for the rest of the scientists, the medical establishment, and the public to become aware as well. This understanding has enormous healing implications for people with brain injuries and other neurological damage—or for those who have simply watched too much mind-numbing TV or played too many video games.

immediately afterward."⁴²⁷ The socioeconomic status (SES) of the children was also examined, because people in different economic and social groups use television differently. "A longitudinal Swedish study reports that 'high achievers' used television as a complement to school learning, whereas 'low achievers' used television as a substitute for it. . . . Television viewing in a general population may serve to exacerbate disparities in cognitive outcomes between high-SES and low-SES households."⁴²⁸ [emphasis added]

In general:

Heavy television viewing by children is worrisome because of the possible negative effects of such viewing on cognitive outcomes. A randomized trial of television reduction among 6-year-olds showed a modest, but significant, improvement in performance IQ and attention time on cognitive tasks associated with experimentally induced reductions in television viewing over a 6-week period. First graders who depended heavily on television and video games for narrative foundations in a story-writing workshop were less able than other students to develop their skills throughout the course of the workshop, and the problem was disproportionately characteristic of minority students. Television and video have been shown to discourage reflection and interpretation and to depress imagination and creativity. . . . For very young children the [TV watching] effects are negative, while for preschool children they can be constructive, at least in some domains. . . . The American Academy of Pediatrics . . . recommends no screen time for children younger than 2 years and only high-quality, age-appropriate [educational TV] viewing thereafter. Clearly, a very substantial portion of television as it is actually watched by children does not meet these recommendations. . . . Parents may need to be advised to undertake greater efforts to steer their children toward educational television and/or reduce overall television viewing time.⁴²⁹

Educational TV can indeed be beneficial. A 2015 study, "Early Childhood Education by MOOC: Lessons from Sesame Street," showed clear "evidence that watching the show generated an immediate and sizeable increase in test scores. . . . *Sesame Street* accomplished its goal of improving school readiness; preschool-aged children . . . were more likely to advance through school as appropriate for their age. This effect is particularly pronounced for boys and non-Hispanic, black children, as well as children living in economically disadvantaged areas."⁴³⁰

There's one more aspect of impaired brain function I want to mention. In 2006, New York state economics professor Michael Waldman was sorely challenged when four months after his daughter was born, his 2½-year-old son was diagnosed with autism. Waldman explored the home environment to see if anything had changed (besides the recent birth itself). He realized that because of the new baby, he and his wife were unable to pay as much attention to their son as they had prior to the birth. "[My son] had been watching much more television during that time, because we were so busy with my daughter. So I turned off the TV," Waldman remarked. "On a day to day basis, we didn't notice a change. But week to week and month to month, the change was dramatic. He was making rapid progress. Within six to eight months, all of his attention and language problems were gone."⁴³¹ After doing research, Waldman understood that autistic children suffer from highly abnormal activity in the visual-processing areas of the brain. So he and two colleagues investigated further to determine if autism was in any way related to TV watching.

What Waldman and his colleagues found was that the rise in childhood autism coincided with the popularity of VCRs and cable TV in the 1980s. Then they wondered if the rise in autism also correlates to bad weather, because it increases the amount of time that children spend indoors and are thus likely to watch more TV. They indeed did find that in rainy and snowy areas of the US, children watched more TV. And yes, there was a rise in autism rates.

Our precipitation tests indicate that just under forty percent of autism diagnoses in the three states studied is the result of television watching due to precipitation, while our cable tests indicate that approximately seventeen percent of the growth in autism in California and Pennsylvania during the 1970s and 1980s is due to the growth of cable television. These findings are consistent with early childhood television viewing being an important trigger for autism.⁴³²

To be fair, the authors did mention the possibility of indoor toxins, and not TV, which would affect the children adversely. And in a later, 2012 paper, "Positive and Negative Mental Health Consequences of Early Childhood Television Watching,"⁴³³ they hypothesized that the lack of sunshine (and hence, Vitamin D) could also contribute to autism.

As you might imagine, Waldman's papers were not well received by most of the establishment medical community (or the entertainment industry!), which used his profession as an economist to discredit his theory. Not many parents wanted to consider that he could be right, either. Of course autism can have numerous triggers: vaccines, poor nutrition, chemical exposure. And of course, not every child who watches a lot of TV develops autism. But at the very least, the impact of increased TV viewing on impaired cognition in general—whether or not it's autism specifically—cannot be denied. Note that the Amish, which is a religious group that lives simply and doesn't use electricity or watch television (or vaccinate), has almost no cases of autism.

Abnormal eye movements are also produced during video games, due to the spinning, twirling, flashing, shattering, zig-zagging, and exploding of objects. Without natural eye movements, over time our brain function—and hence our thinking processes—can become impaired from video games, whether they are played on a TV, iPad®, or iPod®.

Hypnotic Suggestibility

Television programs and films can lull the viewer into a mild, or even deep, hypnotic trance by using sound and light. The sound is often loud music with a rhythmic, repetitive beat. Advertisements interspersed with the "regular" programming use sound—mostly abnormally loud, fever-pitch speech patterns (characteristic of all audio-content ads)—to make the audience fixate on the message. The light takes the form of images that appear onscreen rapidly, often in visually dizzying ways. They can appear in rhythmical patterns, just like the music.

A hypnotic state can also be caused by the television's flicker rate. *Flickers* are the visible on-off pulses, or cycles of light, in the pixels—tiny modules comprising the picture—that are in some types of TV screens. The pixels, needing to be "refreshed," are switched on and off very rapidly. (Old style cathode ray tubes had very noticeable flickers. In modern plasma screens, electrons excite gases in the modules at regular intervals. The more expensive modern TVs have faster pulse rates than cheaper ones.) Tests measuring flicker rates concluded that some of these flickers induce alpha brain waves, whose range is between 8 Hz and 12 Hz (Hertz, or cycles per second). The brain becomes *entrained*—brought into the same rhythm—by these pulsed signals, whether they're in the form of sound, recognizable images, or flickering light.

iPhones and iPads Stunt Children's Growth

Every 30 minutes spent in front of a screen can delay speech development by 49 percent in children younger than two . . .

By the age of two or three, infants should typically be able to communicate in sentences between three to four words. However, [researchers found that] children who spent a majority of their time on handheld devices struggled with their communication skills. . . .

Every hour an infant spent on a smart tablet device was linked to 16 minutes of less sleep . . . [because the] light emitted from these devices suppresses the production of the sleep hormone, melatonin. . . .

During the first few years in life . . . essential neural pathways are built. Between the ages of zero and two, the infant's brain triples in size. Typically this is the time when the child learns how to interact with a parent's touch, voice, and other external stimuli. However, . . . children who merely just interact with a computer screen . . . lack concentration and often find it difficult to develop deeply personal relationships.

Hypnotists purposely induce an alpha state—trance—in their clients, so they can more easily plant suggestions in the person's subconscious mind. This is done at the request of the client, who has purposely enlisted the hypnotist's aid to achieve a desired goal. But what if a TV watcher isn't aware of receiving a subliminal message, while being in a TV-induced alpha state?

Video games create the same issues. Viewers are overloaded with information; everything, positive or negative, goes right into the brain. One study of video games revealed a lowered blood flow in the brains of players. Might this reduce (or reflect) a loss of emotional control and the inability to resist subliminal input? All advertising uses the principles of hypnosis. If someone is repeatedly bombarded, the message is "programmed" right into the brain. This rarely occurs on a conscious level.

Hyperarousal

Electronic media can induce both hyperarousal and hypnotic effects on the brain. Hyperarousal, which like its counterpart manifests as biochemical and neurological changes, occurs in response to many different types of media: films, TV programs and computer games, especially those of the horror or violent genres. Following is a brief summary of the arousal mechanism.

Normally, during a frightening, dangerous or potentially threatening situation, adrenaline—the fight-or-flight hormone secreted by the adrenal glands—is stimulated to impel the person to fight or flee. The *sympathetic nervous system*—which is the defensive aspect of the autonomic (automatic, or involuntary) nervous system—is also stimulated. Among the many physiological responses, the pupils dilate (allowing more light to enter the pupil, so the individual is literally blinded by fear). The saliva glands slow or stop saliva production, making the mouth literally dry with fright. Oxygen consumption increases. Even the digestion slows or stops.

Extreme stress changes our biochemicals too. The calming neurotransmitter *serotonin* is decreased, which increases the vigilance and startle responses. The neurotransmitter *glutamate* is released into the brain, which is responsible for feelings of dissociation, numbness, addictions, panic, and anxiety. GABA (short for *gamma-aminobutyric acid*) is a natural tranquilizer, the counterpart of glutamate. It makes us feel peaceful and easygoing. When glutamate levels rise, GABA levels fall. Glutamate levels also rise when the cell receptors become less sensitive to GABA—which, again, occurs under stress.

Normally, when the source of danger or stress passes, adrenaline secretion ceases, the relaxation neurotransmitters again flow and calm the brain, and the body shifts into the *parasympathetic nervous system* mode (the relaxation side of the autonomic nervous system). Problems begin if the danger continues. The fight-or-flight response is designed for short periods, because "constant danger" is a contradiction in terms and the body was never meant to remain in a chronic survival mode without rest periods. But with repeated, high-energy fight-or-flight stimulation, two things commonly occur. The neurotransmitters that help us feel relaxed, creative and optimistic become depleted. And the adrenals become depleted, eventually shutting down altogether.

What happens to individuals who have exhausted their reserves? Living in a state of unease due to unbalanced neurotransmitters, they develop addictions such as coffee, sugar, stimulants, drugs, or computer games. They might be regarded as addicts because of their need for stimulation, but they're attempting to respond to a legitimate biological need: the replenishing of their adrenal hormones and brain neurotransmitters. The psychological counterpart to this physiological numbing and depletion is usually emotional numbing and depletion. One might feel a need to increase the amount and intensity of stimuli in order to make any adrenaline at all. You may have heard someone say, "I don't feel alive unless I'm putting myself in danger." Some people become thrill seekers, engaging

in high-energy sports that carry a risk of injury or loss of life. Others might gravitate toward violent video games and films in an attempt to force their bodies to produce the biochemicals that have become drained. This is why susceptible children who are constantly exposed to violent acts become *desensitized*, or less emotionally affected by them. Such individuals may feel an increased need for more violent media—or actually seek real violence in their personal lives—simply to feel “alive” again.

Those who claim that the media’s portrayal of murders and other horrific crimes does not foster additional violence in real life, point out (with some justification) that an unloving family life, poverty, and poor diet could account for violent crime. They say that watching violence, or behaving in violent ways vicariously through make-believe characters, actually helps people discharge excess aggression that they normally wouldn’t be able to purge. Inevitably, they cite studies supporting the view that violent programs are helpful. However, the overwhelming majority of research shows that actual crime levels rise when media violence is watched. Brad J. Bushman, author of “The effects of violent video games. Do they affect our behavior?”, summarizes the literature:

Some people claim that violent video games are good for you. Some players believe that violent video games are cathartic (i.e., they allow players to release pent up anger into harmless channels). The scientific evidence directly contradicts this idea. Over 130 studies have been conducted on over 130,000 participants around the world (Anderson et al., 2010). These studies show that violent video games increase aggressive thoughts, angry feelings, physiological arousal (e.g., heart rate, blood pressure), and aggressive behavior. Violent games also decrease helping behavior and feelings of empathy for others.⁴³⁴

Bushman writes that while TV might or might not increase violent tendencies, video games definitely do, because television watching is passive and video games require active participation. He cites a 2007 study.

Players of violent video games are more likely to identify with a violent character. If the game is a first person shooter, players have the same visual perspective as the killer. If the game is third person, the player controls the actions of the violent character from a more distant visual perspective. In a violent TV program, viewers might or might not identify with a violent character. People are more likely to behave aggressively themselves when they identify with a violent character.⁴³⁵

Also reinforcing violent behavior are rules that are standard for all violent video games: they directly reward violent behavior by granting points or by allowing players to advance to the next game level. “In some games,” writes Bushman, “players are rewarded through verbal praise, such as hearing the words ‘Nice shot!’ after killing an enemy. It is well known that rewarding behavior increases its frequency.”⁴³⁶ (This appears to be different for some war veterans suffering from post-traumatic stress disorder. A number of studies have shown that killing virtual enemies in violent video games may help traumatized ex-soldiers develop feelings of having control over negative or frightening events.)

“Hi-tech maps of the mind,” writes one reporter, “show that computer games are damaging brain development and could lead to children being unable to control violent behaviour.” This is not only due to the violence inherent in such games, but, as brain scans have shown, the only portions of the brain stimulated by computer games are those “associated with vision and movement. . . . *The students who played computer games were halting the process of brain development*”—specifically, the frontal lobe of the cerebral cortex, which governs thinking, speaking, decision making, and impulse control—and thus was “affecting their ability to control potentially anti-social elements of their behaviour.” [emphasis added]⁴³⁷

In contrast, arithmetic pursuits

stimulated brain activity in both the left and right hemispheres of the frontal lobe—the area of the brain most associated with learning, memory and emotion. . . . Whenever you use self-control to refrain from lashing out or doing something you should not, the frontal lobe is hard at work. Children often do things they shouldn’t because their frontal lobes are underdeveloped. The more work done to thicken the fibres connecting the neurons in this part of the brain, the better the child’s ability will be to control their behaviour. The more this area is stimulated, the more these fibres will thicken.⁴³⁸

Not surprisingly, the entertainment industry has refuted any data showing the relationship of media to real-life violence. “Most Americans,” Bushman reports, “aren’t even aware that the U.S. Surgeon General issued a warning about TV violence. Perhaps this is because most Americans get their information from the mass media. The entertainment industry is probably reluctant to admit that they are marketing a harmful product, much like the tobacco industry was reluctant to admit that they were marketing a harmful product.”⁴³⁹

Digital Media Impedes Relating

Are young people losing the ability to read emotions in our digital world? Scientists report that sixth-graders who went five days without even glancing at a smartphone, television or other screen did substantially better at reading emotions than sixth-graders from the same school who, as usual, spent hours each day looking at their smartphones and other screens. . . .

"Many people are looking at the benefits of digital media in education, and not many are looking at the costs," said Patricia Greenfield, a distinguished professor of psychology in the UCLA College and senior author of the study [published in the October 2014 edition of *Computers in Human Behavior*]. "Decreased sensitivity to emotional cues—losing the ability to understand the emotions of other people—is one of the costs." . . . The psychologists studied [fifty-one participants who lived for five days at a nature and science camp and fifty-four remained at home] . . . The camp doesn't allow students to use electronic devices . . . children who had been at the camp improved significantly over the five days in their ability to read facial emotions and other nonverbal cues to emotion, compared with the students who continued to use their media devices. . . . The findings applied equally to both boys and girls. . . .

"Social interaction is needed to develop skills in understanding the emotions of other people" [Greenfield said]. . . . [Another researcher, Yalda] Uhls said that emoticons are a poor substitute for face-to-face communication: "We are social creatures. We need device-free time."

Media violence, even when packaged as entertainment, behaves like sophisticated advertisements with profound social and interpersonal implications. Depending on the movie, TV program or video game, children who regularly view violence are taught that it's a normal and necessary—and therefore, correct—part of life. They model their behavior after their violent heroes, not seeing anything amiss. However, this 2017 research study is just the beginning of more scientific proofs that some people already know intuitively. "Cool, callous and in control: superior inhibitory control in frequent players of video games with violent content," describes "robust associations among violent media exposure, increased aggressive behavior, and decreased empathy. Preliminary research indicates that frequent players of violent video games may have differences in emotional and cognitive processes compared to infrequent or nonplayers."⁴⁴⁰

Collateral Damage

Like so many people, I have been profoundly influenced by electronics. Computers are essential for my livelihood. The Internet helps me with research. If I get lost while traveling, I can use the cyber maps on my cell phone. I enjoy streaming my favorite programs online without commercials. And iPads® and smart phones can be fun. A gem-bursting game helps me relax; the instant victory of a winning game feels like an antidote to my long-term writing projects that don't provide instant gratification. However, I limit my time with games, because after a point I get headaches and my eyes hurt. A review of the data, plus my gut instinct, tell me that the price we pay for relying so much on electronic media is much too high.

One obvious disadvantage of electronic media is that people are sitting immobile for huge periods instead of being physically active. More than one-third of the world's population is overweight or obese. Another drawback is the harmful electromagnetic radiation emitted by these devices (see the beginning of this chapter). Also, the strain from an unnatural neck position (such as when texting or using a smart phone for games) is causing serious injuries.

Perhaps the most serious, far-reaching effect of this media is that people aren't learning how to authentically connect with themselves or each other (see Sidebar, "Digital Media Impedes Relating"). Parents give their toddlers smart phones or iPads® to quiet them when they're having temper tantrums. Even babies are playing with this technology. During social events, teenagers and even adults text and take photos instead of talking to the live person in front of them. Why play with or relate to others—which requires effort and emotional risks—when it's easier to receive instant gratification, without emotional entanglement, from a screen? If dependent, neurologically immature children and teens have easy access to screen technology, what are they being taught? The earlier children are hooked, the harder it is to remove the electronics later. There's a good reason why Steve Jobs, founder of the Apple electronic media empire, didn't give his own children iPads®. Likewise, Microsoft founder Bill Gates didn't give his children smart phones until they were in high school. What does that tell you?

Our brains, and especially the brains of children who haven't known anything else, are becoming permanently rewired. What will be the repercussions, on a global scale, if neurological pathways and neurotransmitter levels are so radically altered? It's easier to control people whose creative thinking and behavior are impaired.

Electronic media has exceeded its potential as a useful tool. Instead, it has become just one more legal, addictive drug. People have become insular, gaming and texting themselves into oblivion. Surely there are better options.

BIG PHARMA'S CAMPAIGN AGAINST NUTRITIONAL SUPPLEMENTS

Bullying Tactics to Restrict Natural Remedies

It's no exaggeration to state that the FDA is outright hostile to natural methods that interfere with profits from Big Pharma. Considering that the FDA—a federal agency that's supposed to be objective—receives money from pharmaceutical companies, and is staffed by former drug company representatives, this hostility is no surprise.

As we have seen, dangerous drugs are rarely removed from the market. But government regulations are quite different for natural substances such as herbs. Despite the fact that most herbs are much safer than patented pharmaceuticals, botanicals as well as vitamin and mineral supplements are subject to substantially more scrutiny and restrictions. Also, data supporting the safety and effectiveness of nutrients is usually from sources independent of the supplement manufacturer—as opposed to the drug company-sponsored studies upon which the FDA relies to guarantee drug safety.

In the mainstream media, damning articles on holistic modalities are much more common than damning reports on allopathic treatments. Consider the following excerpt from “How to Recognize a Quack,” which appeared in *The New York Times* in 1988. Even then, the author Jane Brody—who regularly wrote for that newspaper's science section—was writing articles clearly intended to discredit natural therapies. From our perspective today, the article might be considered humorous if it wasn't in a position to do so much damage. This was thirty years ago, before holistic therapies were routinely incorporated into the health regimens of the public majority. Brody began by advising readers to beware of “fraudulent” practitioners.

The practitioner insists that most doctors, the Food and Drug Administration and professional organizations such as the American Medical Association don't know what they're talking about with regard to your health. He may even claim to be persecuted by the medical establishment.

The practitioner has no training in nutrition or food science but may display a string of spurious credentials. . . . Dr. Stephen Barrett, a leader in exposing health frauds and editor of the newsletter Nutrition Forum . . . recommends avoiding nutrition advisers who belong to . . . organizations that do not require their members to have degrees from accredited institutions.

His nutrition education is not based on scientifically established facts. He may have

a degree such as Doctor of Naturopathy (ND), Certified Herbologist (CH), Doctor of Chiropractic (DC), Registered Healthologist (RH) or Certified Acupuncturist (CA).

The counselor claims that modern methods of processing, storing and shipping foods strip them of key nutrients and that people can't possibly get a balanced diet without vitamin and mineral supplements.

He uses unproved diagnostic methods and treatments, such as hair analysis. He espouses “superfoods” and “supernutrients” and may even sell the remedies he prescribes.⁴⁴¹

Stephen Barrett, on whose data Brody relied to write her article, was (and still is) a delicensed doctor. Relatively unknown then, Barrett was later famous as the founder of Quackwatch (renamed Casewatch), an organization that specializes in slandering everything and everyone holistic. Under the organization's auspices, Barrett sued over forty holistic practitioners, claiming that the natural remedies they used were ineffective or harmful. He never won a lawsuit, but he did receive plenty of negative publicity for his habit of filing baseless, defamatory lawsuits. On more than one occasion, the presiding judge harshly reprimanded him for attempting to stifle free speech and freedom of health care choice. Coverage of one trial by a Canadian health organization provides more detail.

At trial, under a heated cross-examination . . . Barrett conceded that he was not a Medical Board Certified psychiatrist because he had failed the certification exam. This was a major revelation since Barrett had provided supposed expert testimony as a psychiatrist and had testified in numerous court cases.

Barrett also had said that he was a legal expert even though he had no formal legal training. During the course of his examination, Barrett also had to concede his ties to the AMA, Federal Trade Commission (FTC) and Food & Drug Administration (FDA).⁴⁴²

Today, studies favorably evaluating the effectiveness of acupuncture and herbs are published in serious medical journals. Over fifty percent of the public employs one or more holistic modality (including chiropractic), but this doesn't stop mainstream media from maligning natural therapies. In a much more recent article by Brody—“Americans Gamble On Herbs As Medicine”—note the emotionally charged word “gamble,” as if it were a self-evident, universal truth that drugs are so much more

DRUG INTERACTIONS WITH HERBS AND NUTRITIONAL SUPPLEMENTS

Periodically, the media warns about unwanted interactions between drugs and nutritional supplements, or drugs and herbs. The problem of unwanted interactions is quite real, because a supplement or herb may cause the body to respond in ways that contradicts or counteracts the (desired) effects of a drug. Conversely, a supplement might augment a drug's effect, thus making the drug's effects even stronger. Most of the time, neither doctors nor those under their care are versed in these interactions. The possibility of unwanted effects is further compounded because many people don't tell their doctor that they are taking herbs and/or supplements (or even other pharmaceuticals) along with the prescribed drug.

The ways in which interaction reports are written often demonize the nutrients and herbs without giving a more complete, functional description of what is really occurring. The information below offers the facts from two different viewpoints. The allopathic angle, summarized from several sources (while remaining faithful to their tone), warns about herbs and other nutritional supplements as though they are interferences. The holistic viewpoint, which is mine, explains the *meaning* of these interactions, thus giving the reader the option to make an informed choice.

Herb/Nutrient	Allopathic Angle	Holistic Perspective
Bromelain	Can increase effects of blood-thinning drugs and tetracycline antibiotics.	Blood-thinning drugs and tetracycline antibiotics may become more potent when the subject consumes bromelain, a naturally-occurring enzyme that catalyzes other chemical reactions. Bromelain also has natural anti-inflammatory effects.
Echinacea	Might counteract immunosuppressant drugs such as glucocorticoids taken for lupus and rheumatoid arthritis. Might increase side effects of methotrexate.	Immunosuppressant drugs taken for lupus and rheumatoid arthritis are less effective if the subject takes echinacea because echinacea increases the production, motility and effectiveness of white blood cells. Rather than trying to eliminate symptoms by suppressing an overactive immune response, why not deal with the root cause. The noxious effects of methotrexate—called “side” effects to prevent us from seeing that all its effects are “primary”—are noticed more by the person who takes echinacea because echinacea stimulates the body's defense cells to do their job. One such task is to remove all poisons from the system.
Evening Primrose Oil	Can counteract the effects of anti-convulsant drugs.	Anti-convulsant drugs do not work as well when the subject consumes evening primrose oil, which contains naturally-occurring fatty acids that feed the brain and nervous system. We might want to look at the relationship of diet and toxins to convulsions.
Vitamin E	Can increase effects of blood-thinning drugs, aspirin, and some herbs.	Blood-thinning drugs and herbs work even better when Vitamin E is consumed. Vitamin E intake should be reduced to no more than 200 IU per day at least two weeks prior to any surgery; anything above that increases the risk of bleeding.
Fish Oil	Can increase effects of blood-thinning drugs, aspirin, and some herbs.	Blood-thinning drugs and herbs work even better when fish oils are consumed. Consider not taking the drug or herb and eat fish oil, a food, instead. (Molecularly distilled fish oil supplements are free of mercury and other dangerous heavy metals.) Decrease fish oil intake at least two weeks prior to surgery to discourage possibility of excess bleeding.
Gamma Linolenic Acid (GLA)	Can increase effects of blood-thinning drugs, aspirin, and some herbs.	See “Vitamin E” and “Fish Oil.” The same logic applies to GLA.

Herb/Nutrient	Allopathic Angle	Holistic Perspective
Garlic	Can increase effects of blood-thinning drugs and herbs.	See "Vitamin E" and "Fish Oil." The same logic applies to garlic.
Ginger	Can increase NSAID side effects and effects of blood-thinning drugs and herbs.	See "Vitamin E" and "Fish Oil." The same logic applies to ginger.
Ginkgo biloba	Can increase effects of blood-thinning drugs and herbs.	See "Vitamin E" and "Fish Oil." The same logic applies to ginkgo.
Folic Acid (synthetic); Methylfolate (bio-available)	Interferes with methotrexate; ask your doctor how to take it.	The intended effects of methotrexate are lessened or altered if the subject consumes folate (folic acid), although the warnings don't indicate if it's at the same time or a different time in the same day. Be aware that folate is an essential nutrient. As most people are deficient in folate, ask for what purposes methotrexate is being taken, and see if there are safer alternatives to the drug.
Ginseng	Can increase effects of blood-thinning drugs, glucocorticoids and estrogens; shouldn't be used by those with diabetes.	See "Vitamin E" and "Fish Oil"; the same logic applies to ginseng. There are many causes of high blood sugar. Therefore, the different physiological and biological causes of diabetes should be investigated before one blanket statement can be made about the effects of an herb, which may or may not address the root causes.
Kava Kava	Can increase effects of alcohol, sedatives and tranquilizers.	Effects of alcohol, sedatives and tranquilizers may be increased by Kava Kava. This suggests that safe, less potent substitutes for sedatives and tranquilizers could be used, whose effects might be augmented by controlled amounts of Kava Kava.
Magnesium	May interact with blood pressure medications.	Blood pressure medications may interact with magnesium. Magnesium deficiency has been proven to be a factor in so many cases of heart attacks and circulatory disorders, that most hospitals immediately put people with heart attacks on intravenous magnesium as soon as they visit the emergency room. If you have a heart problem, check for magnesium deficiency before resorting to taking drugs with unwanted "side" effects.
St. John's Wort	May enhance effects of narcotics, alcohol, and antidepressants; increase risk of sunburn; interfere with iron absorption.	Narcotics, alcohol, and antidepressants are dangerous drugs that substitute for the body's natural functions and may interfere with the pharmacological action of St. John's Wort. European studies show St. John's Wort to be safe and effective in alleviating depression. Note, however, that this herb may negatively interact with the amino acid supplement 5-Hydroxytryptophan (5-HTP), and cause heart palpitations.
Valerian	Can increase the effects of sedatives and tranquilizers.	Sedatives and tranquilizers can increase the effects of valerian root, a safe natural herb that has been used for centuries.
Zinc	Can counteract effects of immunosuppressant drugs.	Zinc is essential for immune cell function. The idea is to deprive immune cells of this vital nutrient in order to disable them. But rather than deprive the body of an essential mineral in an attempt to eliminate symptoms, we should deal with the root cause of the problem.

effective and safe than herbs. Brody's claim that "scores of products [exact number unspecified] sold in the United States are listed by European and American authorities as ineffective, unsafe or both," is simply not supported by reputable research. The "serious side effects" that she says are linked to herbal remedies—"high blood pressure, life-threatening allergic reactions, heart rhythm abnormalities, mania, kidney failure and liver damage"⁴⁴³—are less severe, proportionately fewer in number, and statistically less significant than the effects of allopathic drugs. Of course, any substance powerful enough to change the biochemical terrain of the body must be studied, treated respectfully, and correctly used. *Organically grown or wild-gathered herbs, when properly used, are generally not toxic.*

To Brody's charge that sassafras and comfrey "contain known carcinogens,"⁴⁴⁴ we must ask, "What are those carcinogens exactly, and what data supports this claim?" It's often more useful, to know what information has been omitted rather than what has been included. When a so-called "active ingredient" is removed from its herbal matrix, it causes reactions that wouldn't occur had the whole plant (or more parts of the plant) been consumed. Drug-oriented researchers isolate from an herb what they perceive as the "active" ingredient. They feed it in ridiculously high amounts (which even a human wouldn't consume) to laboratory animals. Then they denounce the herb as invalid because the animals sicken or die.

Faulty tests are common. Earlier I discussed the inaccurate results obtained when drugs meant to be administered orally are injected for tests. For nutrients and herbs, lab animals are often injected, even though humans would normally take the substance orally. Vitamins tested for tolerance levels are injected. But

except for intramuscular Vitamin B12 and intravenous Vitamin C (which must be administered by a licensed medical professional), nutritional supplements are rarely taken via injection. Nevertheless, if adverse reactions are reported when substances meant to be consumed are injected instead, this can be used by researchers to "prove" that the substance is harmful.

When doing tests, it's important to know how the substance is supposed to be used. Many foods and ordinarily benign materials can be harmful if consumed in unusual ways or in abnormally concentrated amounts. We would have to continually ingest excessively high doses of some herbs, over a long period of time, to be harmed. On the other hand, some parts of a plant can be poisonous while other parts are beneficial. One good example is rhubarb. Due to the high oxalic acid content, its leaves are poisonous and when ingested in large enough amounts, can cause cramping, nausea and even death. Cooks discard the leaves, but cook the stalks and make them into pies.

Brody did raise some valid points in that 1988 article. She discussed potentially huge markups in price, dishonest manufacturers whose products don't contain what the label claims, and an herb's lack of effectiveness due to inferior plants, or the ways in which the herbs are processed. However, she failed to question why so many people continued to buy herbal remedies if they don't work. Apparently she believed more in the authority of doctors who don't use the herbs, than in the empirical experience of those who do. Admitting her preference for those who choose "established medical remedies" (allopathic) over those who "choose self-medication with plant extracts"⁴⁴⁵ (holistic), she never questioned who has "established" these allopathic "medical remedies" as the one true path.

Snake Oil Vindicated

Snake oil originally came from China, where it was used to alleviate inflammation and pain in rheumatoid arthritis, bursitis, and similar conditions. Chinese laborers, on section gangs doing the grunt work involved in building the railroad tracks to link North America coast to coast, gave it to Europeans with joint pain (bursitis, arthritis). When rubbed on the skin above the pain, snake oil brought relief, the story goes. Patent medicine men ridiculed the claim. [That is why today, people use the term "snake oil" for a remedy that doesn't work.]

In 1989, a nutrition-oriented medical doctor from California decided to find out what snake oil contains. He obtained a sample of the oil from San Francisco's Chinatown, had it analyzed, and found that [out of the one-quarter that is not carrier oil] . . . 25% of the product is oil from Chinese water snakes, which contains 20% of the important Omega 3 derivative eicosapentaenoic acid (EPA) as well as 48% myristic acid, 10% stearic acid (18:0), 14% oleic acid, and 7% linoleic plus arachidonic acids. At 20% EPA, Chinese water snake is the richest known natural source of the parent of [a compound known as] series 3 prostaglandins, which inhibit the production of pro-inflammatory series 2 prostaglandins. Like essential fatty acids and their other derivatives, EPA can be absorbed through our skin. Salmon oil, the next-best source of EPA, contains a maximum of only 18% EPA. Other fish oils contain less.

The bottom line is that traditional snake oil is natural and therapeutic. The snake oil salesman is vindicated.

Fats that Heal, Fats that Kill, 1993

If there wasn't such a growing interest in (or validity to) natural therapies, establishment medicine and its agents wouldn't be trying so hard to bias people against them. Brody still writes for *The New York Times*. Although her bias against natural healing has softened somewhat, she is still an agent for allopathic medicine. Here is a good example of a journalist whose writing is not independent, but conforms to the political, editorial, and advertising agenda of the publication that pays her salary. Few mainstream reporters truly investigate. They don't review a wide enough range of scientific literature, they aren't receptive to credible representatives in the natural health field, and they rarely display common sense or critical thinking. Instead, they allow their biases to dictate what they write. Those who do ask important questions are fired, or harassed until they quit their jobs.

Despite the continual onslaught of mainstream propaganda, many people seem eager to try holistic protocols. It would be refreshing indeed to see the following, from Mike Adams, in *The New York Times*:

The US Food and Drug Administration, the agency that claims to be responsible for protecting consumers from dangerous food and drug products, has just surrendered its primary responsibility. Recently, an FDA advisory panel voted to recommend that a dangerous prescription drug, Tysabri®, which was withdrawn from the market a year ago due to its promoting of a deadly brain disease, should now be put back on the market. . . .

The justification . . . to reinstate a drug with known deadly side effects is based on the idea that patients should now weigh the risks of dangerous drugs and decide for themselves whether the risks outweigh the benefits, if any. . . .

There are enormous problems with this new stance by the FDA. The first is that patients do not have the medical knowledge to understand and interpret the significance of these side effects that will no doubt only be mentioned in small print . . . [and] that most patients will probably ignore. . . . The second problem . . . is that it exposes a wicked double standard: With prescription drugs, patients should be able to weight benefits vs. risks, even for drugs that may kill you. But with herbs and nutritional supplements, no such decision is extended to patients. The FDA merely bans whatever natural substances it wishes, usually based on reports of very small numbers of people being harmed by extremely rare overdoses. . . . The FDA now sees its job as protecting the public

[Conventional, allopathic] medicine in our country has been on a crusade over the last 100 years to wipe out every other form of medicine. One of the things they did that was unique was they lobbied to make words legal only for them to use. Today in the US, only a medical doctor can diagnose a disease, prescribe something, and cure you. Nobody else can say "diagnose," "prescribe" and "cure." That means that nobody can cure you but a medical doctor. . . .

I can't say, "Chaparral is the cure for a tumour." . . . Pharmaceutical drugs are killing hundreds of thousands of people every year . . . In spite of that, they claim that two people were hurt with chaparral, so they have taken it off the market. And these claims aren't even substantiated. . . .

I can't say garlic is the cure for cholesterol or high blood pressure [even though] garlic has been shown to help our white blood cells not only defend us against cancer, but also to increase our ability to destroy tumors . . . Garlic has been found to stimulate inteferon production, enhance natural killer cells, stop tumor growth, and even reduce the associated pain of cancer. Most of the research has been done on cancers of the digestive tract. . . .

They have made the laws. So that makes me look stupid [and] impotent, and it makes the herbs look weak and wimpy. . . . I can't as a herbalist, say that an herb will cure, even though a lot of prescription drugs are made from herbs. This was a tactic by organised medicine to wipe out the opposition, by making them look silly and impotent . . .

They have the words . . . they control the high ground. They can walk out and say, "Yes, if you take this drug, you will cure yourself." But they hired lawyers and got the government behind them. If I say that, I go to jail. It isn't because the herbs don't work and the drugs are better, it's just because they have more money, they lobbied more and got the law passed in their favour. That is why people get this idea that herbs don't cure you.

from "dangerous" herbs while shirking safety responsibilities on truly dangerous prescription drugs. . . .

The FDA's position now comes down to simply this: Everyone needs to be protected from herbs and nutritional supplements, but no one needs to be protected from prescription drugs. . . . If the agency is now merely going to pass through drug safety decisions to doctors and patients, then why do we need the FDA at all? ⁴⁴⁶

Suppressed Natural Cures

There have been so many attempts by the FDA to restrict natural remedies (if not ban them altogether), that it would take an entire book to document them all. This bullying has occurred with vitamins, minerals, amino acids, herbs, and more. Below are just three examples that show the many ways in which this control has been executed.

Ephedra

The stimulant herb *Ephedra sinica* (also called *ma huang*) has been used by the Chinese for over five thousand years. Its relative, *Ephedra viridis*, grows in the American Southwest and has been used for centuries by the Native Americans. The Mormons, who aren't allowed to have coffee, drink ephedra (nicknamed "Mormon tea"). Ephedra opens the air passages. It's helpful for asthma, allergies, colds, fever, headache, and gastrointestinal and urinary tract conditions. Despite its benefits, the FDA has tried to restrict its availability.

FDA intervention began in 2004 when an herbal weight loss supplement began causing considerable "side" (toxic) effects due to its ephedrine content. The problem was, the FDA failed to distinguish between ephedra and ephedrine. Ephedra is the whole herb. Ephedrine is one synthesized chemical of many compounds present in the whole herb.

We were using niacin [Vitamin B3] and niacinamide before the new psychiatric drugs entered the North American market. Our results were better and safer but we had no one to support us. While drug results were more often more dramatic, they were also much more dangerous. Eventually, it turned out that drugs, while helping in the short run and used in small doses, in the long run stopped the process of recovery long before the patients became well, and froze them into a chronic semi-invalid state from which they can not recover as long as they remain on the medication.

Today, 47 years later, orthomolecular vitamin treatment is still relatively unknown. The use of drugs is world wide and sanctioned by powerful drug interests, the professional associations and governments. It seems not to matter that huge numbers of patients are being denied their chance for full recovery. . . . Niacin has . . . been trampled on for the past 40 years by the galloping hordes of professional establishments, the American Psychiatric Association, governments, the FDA, the National Institutes of Mental Health, and by nearly every health-professional organization. It is a wonder that there are any orthomolecular doctors at all.

—Abram Hoffer, MD, PhD
whale.to/a/saul18.html

Another problem that the FDA failed to address was the amount. A 50-mg serving of whole ephedra herb contains only about half a milligram of ephedrine, compared to a comparable dose of synthesized formula, which contains 20 mg of ephedrine. Incredibly, the FDA scientists missed (more likely ignored) this significant difference. They heavily regulated the natural herb, but not the synthetic ephedra alkaloids, which drug companies had been producing for years. Mary Marino writes:

Almost every cold, cough, or allergy product on the market made by the drug companies such as Sudafed®, Actifed®, Advil® cold and cough formula and others contain synthetically produced versions of the ephedra alkaloid pseudoephedrine. These products are readily found on the shelves of almost every grocery store, drug store, convenience store and pharmacy outlet in the country. . . . To say that natural ephedra kills and a synthetic version of one of its alkaloids found in drugs doesn't, is pure hypocrisy.

How can [the FDA] honestly justify banning ephedra which they claim is killing people yet leave all of the pharmaceutical products on the market containing the same alkaloid that occurs naturally in ephedra? . . . If ephedra is as dangerous as the FDA says, why not ban every product in this country that has any trace of ephedra alkaloids in them instead of taking cheap shots at the supplement industry while protecting the pharmaceutical industry? The fact is, natural ephedra products were taking business away from the pharmaceutical industry.⁴⁴⁷

Not surprisingly, the FDA ignored an existing law that was already regulating sales of natural ephedra. This law was so strict *prior* to the newer ban, reports Marino, that all labels bore strict warnings "listing a number of possible contraindications, including warnings that persons under the age of 18 couldn't buy ephedra and shouldn't take ephedra. Some stores even went as far as locking up their ephedra products in special cases behind the counter."⁴⁴⁸ The newer (stricter) ruling was eventually overturned. Also not surprisingly, in some parts of the US and online, high doses of the synthetic analog are still being sold.

The sleight-of-hand that occurred with ephedra is typical. A synthetic version or extract of an herb causes damage; the FDA bans or restricts the original plant; and the synthesized pharmaceutical is still allowed to be sold. This confusion is unnecessary, and the FDA's deception does not appear to be an accident. Unfortunately, an aware consumer must be vigilant at all times. Assume the worst about regulations, stay informed, and ask questions.

Aloe Vera

There are over three hundred species of aloe vera, a succulent (water-storing) plant that grows abundantly in warm climates. Six thousand years ago, Egyptians called it “plant of immortality,” and some Native American tribes have referred to it as “wand of the heaven.”⁴⁴⁹ Aloe is easy to cultivate and grow. Most of the plants, which have a similar chemical profile, contain six natural antiseptic compounds (including hydrogen peroxide), which kill bacteria, fungi and molds, and viruses. Their other compounds include twelve vitamins (including B12), twenty minerals, eighteen amino acids, enzymes, lignins, anthraquinones, saponins, fatty acids, salicylic acid, and sugars. These sugars are also known as *polymannans*. Different polymannans have different molecular sizes; and it’s the size of the molecules that determines their healing applications.

The soothing gel from the aloe leaf is used in herbal remedies, skin gels, toothpastes, drinks, and even cosmetics. The gel, stripped straight from the fresh leaf, or the juice extracted from the leaf, can be rubbed on the skin for insect bites, rashes and burns; poured into open wounds; swallowed to lower blood sugar levels and to eliminate hemorrhoids, stomach ulcers, urinary tract infections and prostate problems; and massaged into the gums for mouth infections.

The species of aloe pertinent to our discussion is *Aloe barbadensis* Miller because of its effect on the body’s immune cells. Of over two hundred scientific papers on aloe’s benefits, some show that the plant calms a hyperactive response or boosts a lethargic response, depending on what’s needed: “In vivo evidence of the immunomodulatory activity of orally administered Aloe vera gel”⁴⁵⁰ and “Studies on Immunomodulatory Activity of Aloe vera.”⁴⁵¹ “Immunomodulatory effects of Aloe vera and its fractions on response of macrophages against *Candida albicans*” states, “Aloe vera has been shown to modulate the immune response.”⁴⁵² Given aloe’s powerful effect on the immune cells, it’s natural that someone would think of using it to cure cancer, and it’s here that our story of FDA suppression begins. This is a typical illustration of how the FDA tries to eliminate any natural remedy that’s inexpensive, safe and effective, and which thus competes with a pharmaceutical poison.

Aloe as a healing agent for cancer was first brought into the spotlight by Dr. Ivan E. Danhof. His credentials are impressive. Holding both MD and PhD degrees (his specialty was in gastroenterology), he published more than eighty research papers, was a Fulbright scholar, worked as

a consultant to several pharmaceutical research institutes, and served on FDA review panels (dealing mainly with gastrointestinal drugs). With an extensive background in nutrition, microbiology, chemistry and herbology, Danhof is considered the world’s leading expert on aloe vera. His nickname is “Father of Aloe.”

It was in the late 1990s that Danhof developed a novel and effective treatment for cancer using aloe. Then called “Albarin,” it’s now referred to as *polymannose extract*, or simply *PME*. PME is a long-chain sugar that naturally exists in many carbohydrates, including aloe. Dr. Danhof removed some undesirable (naturally occurring) toxic compounds from the aloe, and then began clinical trials.

He utilized only the large-molecule PMEs. “The very large molecules,” Danhof explained, “are immune modulating, which have a powerful healing effect on AIDS, cancer and many different immune system disorders. It is also this large molecule that causes the body to produce a natural chemical, tumor necrosis factors, which functions to shut off the blood supply to tumors.”⁴⁵³

**Patients who get well
when they are not
supposed to are not having
spontaneous remissions.
They’re experiencing
self-induced healing.**

—Bernie Seigel, MD
“Mind Over Cancer,” 1988

It was a brilliant strategy to extract and use the desirable PME molecules. The PME “tells” the immune cells exactly what they should be targeting, and how. Thus, the immune cells can efficiently perform the correct jobs instead of arbitrarily attacking normal body tissue and causing an autoimmune response. Danhof, along with a few other astute researchers, understood that the ability of the mannose molecules to induce molecular signalling was even more important than any of their other (albeit excellent) properties. *Molecular signaling* is the ability of a molecule in a substance to affect the behavior of other cells it contacts. The signaling molecule conveys instructions without being consumed itself in a chemical transformation, just as a computer program on a CD or flash drive runs when it’s placed in a computer, but is not destroyed. Aloe carries clear and correct messages, and the implications of this are profound, even beyond a cure for cancer.

For Danhof’s clinical trials, he enlisted the close assistance of medical doctor Daniel Mayer and nutritionist Joseph Di Stefano, who ran two clinics in Florida, US. The PMEs were always injected because the digestive tract has a hard time absorbing them. Cost of the therapy was \$1200 (less than the price of one chemo session), for as many injections as needed, until the person went into remission. This typically occurred between twenty-five and forty injections. No promises of a cure were made. If someone couldn’t afford treatment, therapy was provided at no cost.

The cancer trials were not advertised. People heard about them through friends, relatives, and acquaintances. The clinic treated over one hundred people labeled “terminal,” whom doctors had sent home to die. Ninety-four people survived, with no undesirable effects from the injections: a success rate of about 80%.

Then the problems began—caused not by those who came for treatment, but by establishment doctors. Local oncologists, who were losing business, complained to the FDA. This occurred around the time that the researchers were starting to file paperwork with the FDA to receive approval of Albarin as an IND (investigational new drug) for cancer treatment.

The first raid occurred in early October 2001. John C. Hammell, head of the International Advocates for Health Freedom, reports.

Joe Di Stefano exited his medical clinic at midnight after a long day's work, and was startled to hear strange noises coming from the dumpster in the back.

Trash was strewn all over the ground. He peered over the top of the dumpster and caught two strangers red handed, with rubber gloves on, probing through his dumpster, trespassing on his property without a search warrant. Then he noticed their unmarked car nearby. Obviously they just assumed no one was there late at night.

When Joe demanded to know who they were, and what they thought they were doing in his garbage, they would not identify themselves and had the nerve to say, “We’re looking for boxes.”

“Sure you are,” said Joe, “everyone looks for boxes at midnight in a dumpster with rubber gloves on.” . . . It turned out that these “dumpster divers” were *FDA agents* seeking evidence to obtain a search warrant against Joe Di Stefano’s clinic.

A week later on October 11, 2001, 120 agents from the FDA, DEA, Customs, U.S. Marshall’s Service, Florida Department of Law Enforcement and the Hillsborough County Sheriff’s Office raided Joe Di Stefano and Dr. Mayer’s clinics in Tampa and St. Petersburg, Florida. The home of Joe Di Stefano was also raided. Joe’s personal property, including his children’s computers that they needed to do their schoolwork, was seized as the agents made disparaging and insulting comments to Di Stefano and his wife, Georgeann.

When the FDA agents attacked the clinics, patients were being administered various therapies by IV injection. The law enforcement officials asked the patients if they wanted to be unhooked from their IVs, but not a single one said yes.

Paul Schebell, with stage 4 liver cancer who’d seen marked improvement during three months of treatment, said directly to the FDA raid leader, “We’re all adults here making free will choices. Why don’t you get out of here and leave us alone?”. . . A simultaneous raid occurred against Ivan Danhoff . . . The compounding pharmacist who prepared the aloe extract (Jerry W. Jackson of Allied Pharmacy Services, Arlington, Texas) was also raided.

Seized in the raids were the aloe extract (Albarin), all patients’ charts, along with all computers and other business records. The purpose of the October 11, 2001 FDA raid was to stop cancer patients from being able to use this intravenous form of aloe vera . . . ⁴⁵⁴

In those early clinical trials, Albarin caused tumors to shrink, significantly relieved pain, increased energy levels, and caused remissions in people who had advanced stages of cancer. Interestingly, Dr. Danhof pointed out that Albarin “had a history of being used successfully since 1996 in humans in over 600 patients in the USA, Canada, Mexico, Holland, Belgium, Germany and China.” Danhof emphasized, Hammell reports, “that he goes to great lengths in his lab using spectral chromatography and other analytic methods to produce a safe, pure substance, and that he has tested every batch on himself or his colleague first before giving it to any patients. All aloe utilized was certified organic. . . . it took him over 20 years to perfect the process of producing Albarin, which is extracted through a freeze-drying process.” ⁴⁵⁵

For years, favorable articles on using aloe for cancer (including leukemia) have appeared in medical journals. Some of them are, in order of publication (from 1976): “Tumor inhibitors. 114. Aloe emodin: antileukemic principle isolated from *Rhamnus frangula* L.” [not a typo], ⁴⁵⁶ “Activation of a mouse macrophage cell line by acemannan: the major carbohydrate fraction from *Aloe vera* gel,” ⁴⁵⁷ “The therapeutic potential of *Aloe Vera* in tumor-bearing rats,” ⁴⁵⁸ and “Aloe-emodin is a new type of anticancer agent with selective activity against neuroectodermal tumors.” ⁴⁵⁹

Despite the great promise of using polymannose extract (Albarin) for cancer, the US government ended the treatments. This shouldn’t surprise anyone, considering that the FDA works for Big Pharma and not consumers (see Sidebar, “Who Benefits From FDA ‘Protection?’”). Suppression of natural remedies happens a lot. Unfortunately, most people never hear about it because mainstream media rarely reports the truth. And if there is any truth to some reporting, it’s often distorted.

Pine Oil (Turpentine, Naturally Derived)

Turpentine isn't a drug or supplement, but an example of a natural remedy whose origins and uses have been hidden.

Turpentine—commonly known as the manufactured “rectified paint grade” chemical, which artists use to clean their brushes—wasn't always made from petroleum. In the Middle Ages in Europe, *terebint* referred to a species of tree that was used to produce turpentine. In fact, the tree was nicknamed the “turpentine tree.” Today, *terebinth* is the name for a small Mediterranean tree in the cashew family (*Pistacia terebinthus*), which is also used to produce turpentine. In the United States, turpentine as a healing agent is steam-distilled *without solvents or other additives* from the resins and volatile oils of live coniferous (cone-bearing) trees, especially pine. Like many aromatic plants from which essential oils are obtained—clove, oregano, eucalyptus, sandalwood, cinnamon, peppermint and cedar, to give just a few examples—turpentine contains a broad class of natural chemical compounds called *terpenes*. They are sometimes called *terebenes*, states one dictionary, from “tereb(inth)+ene,” and are used “medicinally.”⁴⁶⁰

Terpene-rich turpentine has been used medicinally for centuries. Dabbed on cotton wool and placed on a wound, it prevented infections. Cotton wool saturated in turpentine was placed on the chest for respiratory infections. The vapors, when inhaled in small amounts, cleared the lungs. For sprains, arthritis and gout, people massaged a mix of turpentine, cooking oil and perhaps camphor—not the poisonous, synthetic, petroleum-based stuff used today in moth balls, but natural camphor oil, made by distilling the bark and wood of the camphor tree. One of turpentine's most popular uses was for parasite elimination. Typically administered on sugar and taken internally, only a teaspoon or less was needed. Turpentine was also used to eliminate fungal infections, taken internally or used externally on toenails and fungus-ridden skin. It has also been used to eliminate head lice.

With even a brief review of history, chemistry, and the origins of words, we can see that the natural plant-based turpentine is very different from its modern namesake. Natural turpentine does have properties that allow it to function as a solvent. However, as with many essential oils, its safety depends on its concentration, how much is used, how it's applied, who is using it, and even how it's stored. Turpentine's fate is similar to that of other “folk” remedies (including camphor). Something is manufactured from synthetic materials, given the same name as the original, and then everything with that name is labeled “not for internal use.” And, as with any potentially caustic compound, turpentine must be treated with care. But suppressing its history and restricting its label doesn't give us the chance to use it wisely—if at all.

Who Benefits From FDA “Protection”?

Most people don't realize how politically influenced the FDA is. Several former FDA officials who now work as consultants for private industry explained this to me. The FDA receives a lot of “complaints” about various products it regulates. When I was first told this, I said, “Do you mean a lot of consumers complain to the FDA?” The answer is no. The FDA defines “complaints” as when a commercial company contacts the FDA and asks them to investigate the activities of a competitor. The purpose of these complaints is to cause problems for the competitor so that the “complaining” company can gain a tactical advantage in the marketplace. The FDA is happy to serve various pharmaceutical interests in this role due to the revolving door between the Agency and certain companies whose interests they protect.

The FDA claims to be a consumer protection agency. The truth is that industry uses the FDA to attack competitors. So when the FDA pretends to have the interests of consumers at heart, always look to who benefits from the FDA's actions. In most cases, it's giant drug companies, the blood banking industry, large food processors, etc. There is relatively little “consumer protection” provided to the American public by the FDA. The FDA aggressively protects the profit margins of industry (especially big drug companies), at the expense of the individual consumer.

Who do you think “complained” to the FDA about Joe Di Stefano and Dr. Mayer's intravenous aloe therapy? It turns out that no cancer patient or their families ever complained. . . . It turns out that more and more cancer patients were choosing this nontoxic alternative therapy instead of chemotherapy. So the oncologists in the area got together to “complain” to the FDA about Joe Di Stefano and Dr. Mayer selling an unapproved cancer drug (aloe extract).

Realizing that these conventional oncologists are part of the monolithic “cancer industry,” the FDA acted with lightning speed to shut down this competitive threat. After all, if the effects of this aloe extract became widely known, it could inhibit sales of highly profitable chemotherapy drugs.

The FDA has historically functioned to protect the profits of the politically well connected. Small companies who discover novel approaches to treat disease seldom survive the FDA's delays in approving paperwork or Gestapo-like raids as were instigated against Joe Di Stefano, et al.

A Few Common Medications Taken by People Over Age 65 and Safe, Effective, Natural Substitutes

*Benefits of these natural substitutes are summarized only briefly.
Do more research, and consult a qualified holistic practitioner.*

Did you know. . .

Among people age 65 or older, 90% take at least one drug per week, more than 40% take more than five different drugs per week, and at least 12% take more than ten different drugs per week.

[data summarized from J. Mark Ruscin and Sunny A. Linnebur, "Introduction to Drug Therapy in the Elderly," Merck Manual website, 2015]

People age 65–79 receive more than 27 prescriptions for new drugs per year.

Type of Drug, Intended to Treat	Is Drug Effective	Some Toxic ("Side") Effects of Drugs	Natural, Non-Drug Replacements	Properties of Natural Replacements
Antidepressant, Anti-Anxiety	To a very limited extent.	Grogginess, confusion, dizziness (leading to falls), constipation, dry mouth, difficulty urinating.	Magnesium arginate (mineral), Vitamin B1. Kava kava (herb). GABA, acronym for gamma-aminobutyric acid (amino acid). L-Phenylalanine (amino acid). L-Tyrosine (amino acid). Tryptophan (amino acid). Cannabis (from legal hemp). <i>Note the high correlation between depression and subclinical hypothyroidism (the condition of having an underactive thyroid gland).</i>	Help anxiety, nervousness. Calms nervous system, helps with sleep without disturbing REM cycle. Helps with focus, stress tolerance, relaxation, optimism and calmness. Helps with addiction control and pain relief. Helps energy, focus and optimism. Helps self-esteem, calmness, optimism, addiction control. Helps with all of the above. <i>Amino acids help the body create neurotransmitters; consult holistic practitioner on their use. See discussion on mind-altering drugs, pages 52–74.</i>
Blood Sugar Regulation (to lower, for diabetes)	To a very limited extent. It's unreliable, because it can cause blood sugar to fall too abruptly and too much.	Kidney failure, diarrhea or constipation, weight gain, dizziness, nausea, stomach cramps, shivering and sweating, skin rash or itch, greater risk of heart attack.	Chromium and Vanadium (minerals), also Vitamin B1 or Thiamine. Carnosine (amino acid). Cloves, black walnut, wormwood (herbs). Shardunika (<i>Gymnema sylvestre</i>), cedar berries, neem, cinnamon, stevia, and perhaps licorice (herbs). A diet low in sugars/carbs, and high in leafy greens.	Help the body metabolize sugars and normalize blood sugar levels. Lowers blood glucose by enhancing insulin sensitivity. If pancreas isn't working properly due to parasites, these anti-parasite herbs help. Help balance blood sugar levels. These replace bread, cake, candy, and other sweets that cause insulin resistance.

Type of Drug, Intended to Treat	Is Drug Effective	Some Toxic ("Side") Effects of Drugs	Natural, Non-Drug Replacements	Properties of Natural Replacements
Blood Thinner (anticoagulant)	Works too well.	Copious bleeding, nosebleeds, nausea, stomach and abdominal pain, bruising, swelling, fatigue, severe headache, dizziness and fainting, weakness, chest pain, shortness of breath, difficulty swallowing.	Vitamin E. Natural molecule is <i>d-alpha</i> -tocopherol; synthetic is <i>d-l-alpha</i> . Mixed (many types of) tocopherols offer more benefits. Vitamin C. Bioflavonoids (Vitamin P). Fish oil. Proteolytic (protein-digesting) enzymes.	Thins blood when taken in amounts of more than 200 IU per day. Also helps repair capillaries. Thins blood, protects cells. Repair capillaries. Thins blood; helps repair brain and nerve tissue. Decrease stickiness of blood.
Cholesterol-Lowering (statin drug)	Works too well.	Headache, muscle ache and inflammation, fatigue, drowsiness, nausea and vomiting, abdominal pain, diarrhea or constipation, skin rash, insomnia, memory loss, confusion, diabetes.	Natural Vitamin E (as above). Alpha lipoic acid (antioxidant naturally made by the body and often needed in larger quantities). Vitamin C. Bioflavonoids (also known as Vitamin P).	All these nutrients fight free radicals. Free radicals cause the unhealthy oxidation of cholesterol (which then becomes dangerous, and provides a rationale for "lowering" it). <i>Cholesterol is made in the body and is needed for proper function of brain, nerves, kidneys, heart and other systems. Often the problem is due to triglyceride, not cholesterol levels. If the liver—which, when malfunctioning, can't regulate cholesterol levels—is clogged, consult a holistic health professional.</i> <i>Eat healthy fats, found in grass fed meats, clean fish, raw butter, and olive, flax, and coconut oils. Also exercise, appropriate to your age and health level.</i>
Diuretic (to eliminate excess water)	Yes. They work so well that they flush out many vitamins and minerals from the body. Thus, these nutrients must be replenished.	Fever, frequent urination, fatigue, abnormal heart rhythm, weakness, skin rash, muscle cramps, dizziness, blurred vision, confusion, sore throat, headache, dehydration, constipation, cough, ringing in ears, vomiting.	Dandelion root, burdock, horsetail (herbs). Fresh parsley (herb and food).	All these herbs exert <i>gentle</i> diuretic action. Together, they strengthen kidneys and liver, and purify blood. Natural diuretic. (Also helps dissolve kidney stones.) <i>Consult an herbalist for full instructions on how to take these herbs. Avoid horsetail if kidney stones are present.</i>

Type of Drug, Intended to Treat	Is Drug Effective	Some Toxic ("Side") Effects of Drugs	Natural, Non-Drug Replacements	Properties of Natural Replacements
Heartburn, Gastritis, Acid Reflux, GERD (gastroesophageal reflux disease)	To a very limited extent.	Headache, abdominal pain, nausea, diarrhea, sore throat, runny nose, dizziness.	Slippery elm bark (herb), L-glutamine (amino acid). Also clay (see Chapter 3). Hydrochloric acid and digestive enzymes (includes protease, lipase, amylase). Mastic gum (resin from the trunk of an evergreen shrub).	Repair the mucous membranes that line the gastrointestinal tract. Hydrochloric acid and these enzymes digest food. Antioxidant, antibacterial and anti-inflammatory, very healing for digestive tract. <i>GERD is usually due to a lack of sufficient hydrochloric acid (made in the stomach to digest food). Too much or too little hydrochloric acid produce similar symptoms. After age 40, our bodies don't produce enough.</i>
Heart Stabilizing (for arrhythmia)	To a very limited extent.	Chest pain, fainting, abnormally fast or slow heartbeat, dizziness, blurred vision, diarrhea or constipation, swollen legs, increased sensitivity to light.	Hawthorne berry (herb). One of the best ways to administer it is in its high-vital-force Gemmotherapy tincture form, the buds and first shoots of the plant. Magnesium (mineral) comes in many forms. For heart muscle, magnesium orotate, magnesium aspartate, or magnesium taurate are optimal, although all forms of magnesium can help. Carnosine (amino acid).	Strengthens heart muscle, repairs blood vessels, and normalizes blood pressure. Food for the heart. (Note: After suffering heart attacks, people are usually put on intravenous magnesium drips in the hospital.) Helps protect muscles, including the heart.
Muscle Relaxant Also see "Sedative."	No.	Grogginess, confusion, dizziness (leading to falls), constipation, dry mouth, difficulty urinating, abnormal heart rhythm, fast or irregular breathing, facial swelling, shortness of breath, skin hives or itching, nausea, blurred vision, muscle weakness, headache, seizures, hallucinations.	Magnesium arginate. Magnesium chloride form, applied topically as "magnesium oil," works very well and allows more of the mineral to be absorbed. Soaking in magnesium sulfate (Epsom salts) is also beneficial, though not as long lasting. Enzymes—especially protease, but also bromelain. Rescue Cream® or T-Relief™ (homeopathic creams).	Tense and painful muscles are often caused or exacerbated by a magnesium deficiency. Enzymes scavenge debris that lodge in muscles and joints, causing pain. Applied topically to sore areas, they relieve pain and help restore tissue function.

Type of Drug, Intended to Treat	Is Drug Effective	Some Toxic ("Side") Effects of Drugs	Natural, Non-Drug Replacements	Properties of Natural Replacements
Non-Steroidal Anti-Inflammatory Drug, or NSAID (typically for arthritis)	Yes, by inhibiting enzymes involved in substances that can cause pain. However, these same enzymes are also needed for other vital functions.	Indigestion, bleeding ulcers, bleeding colon, high blood pressure, and heart failure.	Turmeric root powder (which contains compound called curcumin). Adding black pepper, coconut oil or other fat, and heating the mixture, may aid absorption. Enzymes. Magnesium (mineral). Malic acid (naturally occurring compound present in many foods).	Lessens or eliminates inflammation, protects brain and nerve tissue. See "Muscle Relaxant." See "Muscle Relaxant." Reduces muscle fatigue while increasing strength.
Opioid Pain Reliever (narcotic)	Usually.	Dizziness (leading to falls), hallucinations, confusion, seizures, drowsiness, constipation, nausea, vomiting, muscle pain, anxiety, irritability, and addiction to the drug.	Protease enzymes. Pancreatic enzymes. Other enzymes, including bromelain, papain, serrapeptase, nattokinase, and lumbrokinase. <i>Take enzymes on an empty stomach so they scavenge debris in bloodstream instead of being used for digestion.</i> Vitamin C (high amounts). Cannabis (from legal hemp).	All these enzymes, taken on an empty stomach, reduce or eliminate pain and inflammation by scavenging ("eating") foreign proteins in the body that cause the pain and inflammation. Chemical exposure and diet should be addressed to eliminate the origin of toxic debris. Cleans opioid receptor sites on cells so there's less pain. Attaches to body's receptor sites and eliminates pain.
Osteoporosis	Hardly at all.	Abnormal heart rhythm, throat and chest pain, difficulty swallowing, heartburn, bone loss in the jaw, increased risk of bone fractures. Also incapacitating bone, joint and muscle pain.	Magnesium. (Also see under "Muscle Relaxant.") Boron (mineral). Iodine and Selenium (minerals). Vitamin D3. Phosphorus (mineral). Calcium (mineral), if necessary.	Escorts calcium into the bone. Most people believe they need calcium but usually they're deficient in magnesium. Needed for building bone; helps conserve and utilize calcium and other minerals. Help promote proper bone metabolism. Regulates the uptake of phosphorus and calcium. Helps remodel bones and prevent fractures. The second most abundant mineral in the body, 85% of phosphorus is in the bones and teeth. The most abundant mineral in the body, calcium builds bones, but only if the proper ratios of the other nutrients are also present.

Type of Drug, Intended to Treat	Is Drug Effective	Some Toxic ("Side") Effects of Drugs	Natural, Non-Drug Replacements	Properties of Natural Replacements
Sedative could overlap with Sleeping Pills	To a very limited extent.	Cognitive impairment, anxiety, delirium, hallucinations, aggression, restlessness, depression, suicidal tendencies, dizziness (leading to falls), reduced heart rate, abnormally slowed breathing, and addiction to the drug.	Amino acids, especially Tryptophan which helps with sleep. For details, see "Antidepressant, Anti-Anxiety" on the first page of this chart. Valerian root ¹ , hops ² , kava kava ³ , passion flower ⁴ (herbs). Chamomile tea (herb). Lime tree (Gemmotherapy tincture). Melatonin (hormone).	Supplementing with amino acids (the building blocks of protein) can help the body produce the necessary neurotransmitters, and thus balance the brain and its physical and mental functions, including moods. Often in sleep formulas: relaxes central nervous system and smooth muscles ¹ ; induces sleep by relaxing nerves ² , relaxes muscles and induces sleep ³ , calms nerves, relaxes muscles and alleviates pain. ⁴ Soothing flowers can be drunk as a tea anytime for calmness and relaxation. Calms nervous system. Produced by the pineal gland and sold as a supplement, melatonin helps with immunity as well as sleep and well-being.
Steroid (to help build lean muscle mass in the elderly)	Hardly at all.	Weakened bone, ligaments and tendons, agitation and anxiety, blurred vision, dizziness, abnormal heartbeat, headache, depression and nervousness, shortness of breath, swelling in the limbs, slowed thinking, problems walking or speaking, abdominal and stomach pain, nausea and vomiting.	L-glutamine (amino acid), can be ingested in powder form. Leucine, isoleucine, and valine (amino acids). Carnosine (amino acid). Whey from goats or grass fed cows. Supplement of all amino acids, non-dairy formula.	Builds muscle mass and strength, repairs gut, feeds the brain, improves immune function. Stimulate protein synthesis and regulate protein metabolism. Protects muscles, including heart. Helps body utilize proteins. May help prevent Alzheimer's and Parkinson's. Contains every amino acid, and is easily absorbed and bio-available. Sometimes, dairy intolerant people do well with whey protein <i>isolate</i> , which has the lactose (milk sugars) removed. Make sure whey is from grass fed cows, and that it's cold-processed (with little or no heat, so the valuable nutrients aren't destroyed). Instead of whey, and instead of individual amino acids.

A HOLISTIC, FUNCTIONAL APPROACH TO HEALTH

Substitution and Masking vs. Support

Most allopathic medications either inhibit, or eventually prevent altogether, the body's ability to function on its own. As mentioned earlier, a drug is taken to suppress symptoms, as a substitute for a bodily function, or as a substitute for a bodily substance.

As an example of suppressed symptoms, let's look at a migraine. A drug numbs the nerves, thus preventing messages calling out "Pain!" from reaching the brain. As an example of a bodily function, let's look at constipation. An allopathic doctor may prescribe a muscle relaxant but a holistic naturopath always seeks the cause of the constipation first. The cause may be impacted waste in the colon due to improper diet, parasites or *Candida* that clog the colon, or even inadequate amounts of water, which make the stool hard. With all of these causes, sending the muscles the pharmaceutical message "Relax!" won't address the problem, and in fact may make the constipation worse. Finally, as an example of a bodily product, let's look at thyroxine, a thyroid hormone. If the gland is underactive, thyroxine is prescribed to replace what the gland does not appear to be secreting. But this may cause the thyroid to become more lethargic. Biochemically, the receptor sites for thyroid hormone are sated. They don't "know" or "care" that the hormone they're receiving is from a source outside rather than inside the body. The body's internal sensors know only that there is enough thyroxine circulating in the bloodstream for the moment. So, via a series of biochemical messengers, the thyroid is told to stop producing thyroxine. In turn, this creates the need for a larger drug dose. As the subject becomes even more dependent on externally-provided thyroxine, in time the thyroid gland completely loses its capacity to manufacture hormone and literally atrophies from lack of use. As a result, the subject is forced to take the substitute drug forever. Thus another vicious cycle is created.

In all of the situations I have just described, when a drug is taken over a long enough period of time to mask symptoms, replace a bodily function or replace a bodily substance, the person can become permanently dependent on pharmaceuticals. The liberal use of such drugs is what separates holistic/functional medicine from allopathic medicine.

Allopathic medicine can be welcome and extremely helpful for people in crisis, such as those who require intervention in the form of emergency drugs or immediate surgery. However, allopathic medicine doesn't know what to do for chronic illness (or claims not to know how to

prevent it). The holistic model tries to stimulate repair of the body, but establishment medicine is not interested in the *causes* of degenerative conditions—nor is it interested in helping people recover by giving them what they truly need. In fact, in April 2018, analysts working for Goldman Sachs, one of the largest investment banks in the world, delivered a report to a biotech company in answer to the question, "Is curing patients a sustainable business model?" The title is incredibly revealing. So was the report, which addressed the decrease of "the available pool of treatable patients" in the event that people were actually cured.⁴⁶¹ A person's health and quality of life didn't matter, but the company's bottom line—money—did.

Our goal is to support the body before it reaches the point where radical intervention is necessary, or is the only option. To achieve this goal, we need a holistic approach.

All Parts Are Connected

Western medicine's demand for double-blind studies—based on the premise that this is the only valid way to determine whether a drug, herb or vitamin is effective—is disempowering, and ultimately unscientific. Proponents of this method claim that scientists can determine precisely what the agent of healing does or doesn't do only if the subject is passive. However, the question, "What results are generated by the subject and what results are generated by the drug?" is not the right one to ask. The principle of "active/passive" is based on a dichotomy of "either/or" that doesn't exist in real life. Quantum physicists remind us that one cannot observe something without changing what is being observed. This principle pertains as much to the macrocosmic world as it does to the microcosmic universe. It's *never* the case that people are completely passive agents in their own healing. Simply making a decision to get well—or to participate in a double-blind study, for that matter—can reflect the person's desire to grow or change. When someone takes charge of their own healing, beneficial biochemical and physiological changes occur. Even conventional medicine acknowledges that people who feel in control over their lives produce hormones that help them heal, whereas those who do not feel in control produce noxious biological chemicals that make them feel even sicker.

Neuroscientist Candace Pert illustrates the importance of taking charge of one's own life in her fascinating book, *Molecules of Emotion*.

[My colleagues and I discovered that] The immune system was potentially capable of both sending information to the brain via immunopeptides and of receiving information from the brain via

neuropeptides (which hooked up with receptors on the immune cell surfaces). Our work . . . [pointed] irrefutably to the existence of a chemical mechanism through which the immune system could communicate not only with the endocrine system but with the nervous system and brain, as well. Previous work my colleagues and I had done demonstrated quite convincingly that the brain communicated with many other bodily systems. But the immune system had always been considered separate from the other systems. Now we had definite proof that this was not the case.⁴⁶²

The same theme of biological interconnectedness, expressed from a structural viewpoint, is discussed in *Energy Medicine: The Scientific Basis* by James Oschman.

“A few decades ago,” Oschman writes, “the living cell was visualized as a membrane-bound bag containing a solution of molecules”—which left the interior of the cell to be considered basically “empty.” However, contrary to what many of us learned in high school, a cell in the body “is *not* a bag of solution,” nor a circular outline surrounding empty space.

The more closely biologists and microscopists looked at cells, the more structures they found. With better preparation techniques, electron microscopists began to see within cells the material that the biochemists had been discarding. . . .

We now know that the cell is so filled with filaments and tubes and fibers and trabeculae—collectively called the cytoplasmic matrix or

	Holistic Medicine	Conventional Medicine
Philosophy	Based on the integration of allopathic (MD), osteopathic (DO), naturopathic (ND), energy, and ethno-medicine.	Based on allopathic medicine.
Primary Objective of Care	To promote optimal health and as a byproduct, to prevent and treat disease.	To cure or mitigate disease.
Primary Method of Care	Empower patients to heal themselves by addressing the causes of their disease and facilitating lifestyle changes through health promotion.	Focus on the elimination of physical symptoms.
Diagnosis	Evaluate the whole person through holistic medical history, holistic health score sheet, physical exam, lab data.	Evaluate the body with history, physical exam, lab data.
Primary Care Treatment Options	Love applied to body, mind, and spirit with diet, exercise, environmental measures, attitudinal and behavioral modifications, relationship and spiritual counseling, bioenergy enhancement.	Drugs and surgery.
Secondary Care Treatment Options	Botanical (herbal) medicine, homeopathy, acupuncture, manual medicine, biomolecular therapies, physical therapy, drugs, and surgery.	Diet, exercise, physical therapy, and stress management.
Weaknesses	Shortage of holistic physicians and training programs; time-intensive, requiring a commitment to a healing process, not a quick fix.	Ineffective in preventing and curing chronic disease; expensive.
Strengths	Empowers patients to take responsibility for their own health, and in so doing is cost-effective in treating both acute and chronic illness; therapeutic in preventing and treating chronic disease; and essential in creating optimal health.	Highly therapeutic in treating both acute and life-threatening illness and injuries.

cytoskeleton—that there is little space left for a solution of randomly diffusing . . . molecules. *Virtually all the cell water is bound in particular ways to the cellular framework.* [emphasis added]⁴⁶³

In other words, scientists discovered that the cellular matrix (within the cell) and extracellular matrix (outside the cell) are both comprised of a certain type of delicate connective tissue that links the inside of each cell to the inside of every other cell *throughout the entire body*. (This discovery was unknown for a long time because the very process of preparing cells for viewing under a microscope, and the ways in which enzymes were extracted for examination, destroyed the living matrixes that are a vital part of the cellular structures. Chapter 2 discusses in depth what is possible to miss under a microscope.)

The discovery of this interconnected matrix has enormous ramifications. *It is our connective matrix that allows information to travel instantaneously in the body*—whether that information takes the form of hormones, electromagnetic radiation, or another type of energy. “The boundaries between the cell environment, the cell interior, and the genetic material are not as sharp or as impermeable as we once thought,” Oschman reports. He describes how appreciating this biology can help us understand various healing modalities.

As a hands-on [massage, “Touch For Health,” energy work, or related therapist], what you touch is not merely the skin [which also contains this matrix of tissue]—you contact a . . . living matrix [that] is a continuous and dynamic “supramolecular” webwork, extending into every nook and cranny of the body. . . . In essence, when you touch a human body, you are touching a continuously interconnected system, composed of virtually all of the molecules in the body linked together in an intricate webwork. *The living matrix has no fundamental unit or central aspect, no part that is primary or most basic. The properties of the whole net depend upon the integrated activities of all of the components. Effects on one part of the system can, and do, spread to others.* [emphasis added]⁴⁶⁴

Recognizing the body as a single, unified organism makes it much easier to comprehend why the *intentions* on the part of the healer or health care provider are so important. Intentions, Oschman explains, “give rise to specific patterns of electrical and magnetic activity in the nervous system of the therapist that can spread through their body and into the body of a patient.”⁴⁶⁵

Help the Body Fight Cancer On Its Own? What a Novel Idea!

The Food and Drug Administration on Thursday approved the first of an eagerly awaited new class of cancer drugs that unleashes the body’s immune system to fight tumors.

The drug, which Merck will sell under the name Keytruda, was approved for patients with advanced melanoma who have exhausted other therapies.

Cancer researchers have been almost giddy in the last couple of years about the potential of drugs like Keytruda, which seem to solve a century-old mystery of how cancerous cells manage to evade the body’s immune system.

The answer is that tumors activate brakes on the immune system, preventing it from attacking them. Keytruda is the first drug approved that inhibits the action of one of those brakes, a protein known as PD-1, or programmed death receptor 1. . . .

Keytruda was given accelerated approval by the F.D.A., allowing it to reach the market without the three typical phases of clinical trials needed to show [that] a drug can prolong lives. . . .

But the treatments will not be inexpensive. Merck said Thursday that the drug, known generically as pembrolizumab, would cost about \$12,500 a month, or about \$150,000 a year. . . .

Keytruda’s label warns that it can cause immune system reactions that can damage the lungs, liver, kidney and other organs. However, that warning is not inside a black box, the strongest level of caution.

This phenomenon on the biological level is mirrored in quantum physics. Subatomic particles in their own separate research laboratories have been shown to *communicate*—even across the Atlantic Ocean. In the ether, just like inside and outside biological cells, there exists a matrix consisting of particles that oscillate in response to each other. I discuss this in more detail in Chapter 6.

As it turns out, the oscillations of cells, along with their receptivity to electromagnetic fields, explain how Rife Therapy can restore normal cells as well as kill harmful microorganisms (see Chapters 2 and 4, and Appendix C). Oschman’s book is an excellent resource. He documents the different types of energy (frequencies) on the electromagnetic spectrum, what devices were used to register the various frequencies in the body, and how they can be applied to various methods of healing.

A HOLISTIC APPROACH: THE BASICS

Holistic health cannot be separated from holistic living. In natural medicine, one chooses an orientation and a direction as much as a particular treatment. When you sincerely adopt a holistic framework, your entire approach to life cannot help but shift.

Learning basic principles about the structure, function, and biochemistry of the body is empowering. Although we might (rightly) seek guidance and information from those more knowledgeable, ultimately we all (re)turn to ourselves to discover what is best for us. No one else lives in your body or has your exact experiences, senses, and perceptions.

Mainstream medicine—especially if it's considered the sole healing modality or the only viable one—by definition shackles us to invasive procedures. Equally important, it fortifies the illusion that in order to heal, we must abandon our own abilities and leave our fate in the hands of the so-called experts. Those who relinquish responsibility for their health give up their power, their autonomy, and often their lives.

A 2004 Harris Poll survey showed that a measly “13% of Americans believe that pharmaceutical companies are ‘generally honest and trustworthy,’ putting the industry on a par with tobacco, oil, and managed care companies.”⁴⁶⁶ Twelve years later, a 2016 Gallup poll calculated that the pharmaceutical industry had a “net positive” rating of minus 23, with only the federal government ranking lower.⁴⁶⁷ Nevertheless, people still flock to mainstream doctors and hospitals. Even if a holistic therapy proves effective according to the most stringent requirements, people may still avoid it because they have been trained to denigrate everything that is not considered “standard” treatment. In addition, many people who express interest in holistic modalities may choose allopathic medicine when they become seriously ill—because Western medicine is what they were taught as children. It's familiar, and people tend to be comforted by the familiar during a crisis. Plus, humans tend to adhere to habits. Thus we may choose the path of least resistance, even if we suspect that it may not be beneficial long term.

Sometimes, even those committed to holistic methods find it challenging to continue implementing them if their family and friends think they are being foolish. How many times have you been assaulted with the veiled intimidation tactic, “No one *else* does it that way”?

Unlimited publicity also plays a huge role in keeping some of us attached to Western medicine: there is simply

more public awareness of allopathic modalities than holistic ones. Also, there are many more allopathic doctors than holistic practitioners. All of these factors—combined with the refusal of insurance companies to reimburse for holistic remedies—can discourage all but the most determined souls from pursuing a holistic path.

In the scientific arena, a holistic modality might be evaluated as worthless or harmful not because it's defective, but because the Western standard used to evaluate it is based on limited, linear methods that do not, and cannot, work on living, whole systems. “Simply because a treatment or therapy fails to fit the medical world's concept of accountability,” writes Rife researcher and chiropractor James Bare, “does not mean that it has no merit and should be considered fraudulent. In the final analysis only the results of the treatment [and] the patient's health . . . after treatment are of any importance.”⁴⁶⁸

Dr. Bare points out that despite the enormous amount of wealth it can access, the allopathic medical profession “has not been able to produce satisfactory results. Certainly no practitioner of natural health care would ever make press releases to brag about a 4% to 9% response (responded but still died from the disease) rate from their patients.”⁴⁶⁹

Moreover,

Patients willingly accept the huge physical risks associated with [allopathic] medical care. Yet that same patient and their family has no tolerance for any risk associated with Natural Therapeutics. A 1% or 2% death rate just from the use of anesthesia is completely acceptable, the death of 40,000 people a year from prescribed medications reactions, . . . [the death of] 40,000 people a year from surgery is acceptable, the death of several thousand people a year from improperly administered or incorrect medications is acceptable, the hospitalizing of over 8 million people in 1994 for drug-related mortality and morbidity is tolerated, but not one death or injury from Natural Therapeutics is tolerated.⁴⁷⁰

A Chinese medicine specialist points out the folly of regarding health in such narrow terms as distinct diseases or specific cures, because illness can indicate weakness or imbalance of the entire organism. Once we “seek to overcome those weaknesses,” he writes, we “will very likely end up doing what we would do to be healthy, even if we weren't sick. The motivation here is not to overcome disease, but to help support life.”⁴⁷¹

The most common way
people give up their power
is by thinking they don't
have any.

—Alice Walker
writer and activist
(born 1944)

How many of us live in an environment that fosters self-awareness, encourages the freedom to choose, and supports our uniqueness and creativity? If you have always trusted the government and medical establishment, and believed that they are truly interested in your well-being, some of the material in this chapter may be difficult to process or even feel overwhelming. “Why would people in such positions of power,” you might ask, “want to cause harm to innocent people?”

The answers to this emotionally charged question may not be easy to accept. I do know that part of the answer is about greed and power that allow corporate profits to escalate at the expense of people’s quality of life. But there are deeper psychological and even spiritual issues operating here, too. Some individuals enjoy having complete control over others. It gives them a feeling of power and importance. (This need for power, the desire to coerce and intimidate, indicates an inner emptiness and disconnection from the very source that helps promote good health. I address this in detail in Chapter 6.)

For those desiring a holistic life, what do we do? Is there any hope for increased funding of research for complementary modalities? There is always hope. Hope is a positive emotion that assists in healing. But we need to be realistic too. As long as the money is controlled by the medical-pharmaceutical cartel, funding will be limited for truly innovative natural therapies. The changes requested by attendees in 2004 at a conference, Corporate and Political Influence on Science-based Policymaking—from the disclosure of “financial interests of investigators and funding sources, to a registry of all clinical trials, to comparative rather than placebo controlled trials, to publication of negative data”⁴⁷²—are as pertinent today as they were then. Unfortunately, this indicates how much more needs to be accomplished.

Meanwhile, there’s plenty we can do for ourselves, and that is what this book is about. If you are curious about how holistic protocols can help you, don’t wait until you’re too weak or ill to do your research. Start now!

People who dismiss the corruption in the government and pharmaceutical industry as imaginary, exaggerated, or as the delusions of paranoid souls, are fooling themselves. They may also be leaving themselves vulnerable to a health crisis. After becoming sick, they will find that the medical options available to them do little to prolong their life or augment the quality of their remaining time. However, those who are open to genuine learning, to expanding beyond the conventional status quo mindset, have a much better chance of healing. They are the ones who ask questions, refuse to take “no” for an answer, and get excited about possibilities—including Rife Therapy.

When a “Patient” Becomes a “Client”

The allopathic medical model is intrinsically flawed. Many of the words and phrases used in that system are obviously crafted to obscure. But they’re also meant to enforce an undesirable hierarchy.

The word “patient” enforces this hierarchy in an insidious way. It transforms the client into a weak, obedient and dependent child—with no ability to discriminate and no right to question—while the doctor assumes the role of all-knowing parent or god, whose opinion must be followed even if it’s against the patient’s better judgment or common sense.

Objecting to the “doctor-patient” paradigm is more than linguistic nit-picking. Being a “patient” not only discourages you from helping yourself; it can actively hinder healing. In *Cancer As A Turning Point*, psychologist Lawrence LeShan writes about many cancer “patients” who did exactly what their doctors ordered them to do. Yet despite their eager compliance and strict adherence to protocol, they became weaker and sicker and lost the will to live. By contrast, those who either disobeyed their doctors, or became (from the doctors’ perspective) demanding, irritable and uncooperative, went into remission. Taking responsibility for their own condition, psychologically and emotionally, corresponded to the mobilization of their immune cells which allowed them to heal. The very act of questioning their doctors’ authority meant a positive difference in their attitudes, in their immune response, and how their energy flowed. In short, they took their lives into their own hands.

Understandably, it can be painful to acknowledge the cavalier disregard of human life that pervades industry and some of the highest levels of world governments. But the refusal to be asleep does not mean surrendering to despair. We can use our awareness to circumvent, dislodge, or change the mainstream (dominant) paradigm. There are many ways to participate in the growing global movement for positive transformation. The area of change this book focuses on is health, with an emphasis on holistic modalities and the technology invented by Royal Raymond Rife.

It should be noted that all of Rife’s experiments were conducted within the parameters of allopathic medicine, and that the doctors who supported him were allopathically trained. However, although it can be tempting to use any therapy in a mechanized (allopathic) manner, the chances of healing are infinitely better if you do not. Rife understood the larger, holistic picture—as you will see in Chapter 2.

LIFE CYCLES OF A PATHOGEN: BÉCHAMP VERSUS PASTEUR

Holistic health can sometimes be a “hard sell” in today’s marketplace. As discussed in detail in Chapter 1, the wealthy, corrupt and powerful medical-pharmaceutical industry has launched a sustained campaign to discredit any person, modality, substance and idea that threatens its influence and profits. Drug companies publish biased and fictitious “research” denigrating effective and time-honored remedies. Meanwhile, for their expensive new medicines, they promote fabricated lab tests and clinical trials, making these toxic drugs appear safer and more effective than they actually are.

For almost two centuries, people worldwide have grown up fearing dangerous microorganisms that lurk in our air, water and food, causing infection and plague in hapless victims. This is largely due to a clash between two Frenchmen: chemist Louis Pasteur (who represented Big Pharma) and doctor-pharmacologist Pierre Jacques Antoine Béchamp (who represented holism). While Pasteur’s name is well known today, most people have never even heard of Béchamp. Thus, it’s not difficult to guess who won the war on how we perceive harmful microbes. Once you learn the central issues behind this debate, who won it and why, you will understand why Royal Rife’s technology was so difficult for some people to accept.

Pasteur’s name is recognized by the lay public largely because he championed the widespread process of heating

milk to temperatures high enough to destroy pathogens. In fact, the process is called “pasteurization” in his honor. What most people don’t know is that pasteurization is not as beneficial as we have been led to believe. In fact, the process can cause damage to such an extent that a food is actually dangerous (see Chapter 3, **Food**, for more details on pasteurized and homogenized milk). Few people are aware that of the legitimate ideas and discoveries that Pasteur did present to the world, many were stolen from Béchamp (born 1816), who was far more brilliant than his rival, and who, unlike Pasteur, was a true scientist.

Louis Pasteur, in hypothesizing how people get sick, promoted what became known as the “germ theory” of disease. Briefly, the theory states that bacteria, viruses and fungi are potent and unchanging; they invade the person from an outside source; a particular microbe causes a particular disease; and once we wipe out the germ with medicine, we banish the disease and create health. The problem is, Pasteur’s germ theory was based on research that was not only flawed, but in some cases, outright falsified (just as it is today).

Pasteur and Béchamp were quite different in intellect, training, competence, and temperament. Pasteur, although credentialed in chemistry (and even so, he barely passed his exams), he had no formal schooling in the biological or medical sciences. Béchamp, on the other hand, held many degrees and titles. Among these were Doctor of Medicine, Doctor of Science, Master of Pharmacy, Professor of Medical Chemistry and Pharmacy (at the

Faculty of Medicine, Montpellier University), Professor of Biological Chemistry, Fellow and Professor of Physics and Toxicology, and Dean of the Free Faculty of Medicine (at the University of Lille, France). Among Béchamp's many achievements was the development of an inexpensive way to produce the chemical aniline for France's dye manufacturers. He also saved the silk industry in France from ruin by finding the causes and cures for two diseases that were devastating the silkworm population. Although Pasteur wrote in a correspondence to a colleague, "I have never even touched a silk-worm,"¹ he later claimed credit for having single-handedly rescued the silk industry—a claim so well publicized, that Pasteur was believed due to sheer repetition.

Some of Béchamp's work that Pasteur plagiarized was submitted to the French Academy of Science in Pasteur's name. Science biographer Edith Douglas Hume chronicles in great detail how Pasteur's conclusions sometimes contradicted what his own experiments revealed. She also reports that various chemical procedures suggested by Pasteur to French winemakers and other industry heads were abandoned after they learned that his suggestions would not work.

Despite Béchamp's scientific contributions, his name and achievements have been nearly obliterated from history while the name and achievements of Louis Pasteur are revered. An ironic twist to this tale is that although Pasteur stole scientifically accurate data from Béchamp, it was sometimes so contaminated by Pasteur's own wild speculations that many of Béchamp's improvements and contributions were offset or erased entirely. Perhaps Pasteur's greatest offense was replacing Béchamp's solid evidence about the origin and nature of pathogens with his spurious germ theory. This popular fiction quickly became regarded as irrefutable fact by mainstream scientists and medical doctors. I will discuss the flawed germ theory in a moment—but first, it's worth exploring a bit how this theory became construed as absolute fact.

The answer then (as now) has a lot to do with publicity, politics, and drive. Hume writes of Louis Pasteur that "intense strength of will, acute worldly wisdom and unflagging ambition were the prominent traits of his character."² By contrast,

Antoine Béchamp was utterly indifferent to personal ambition. Never of a pushing temperament, he made no effort to seek out influential acquaintances and advertise his successes to them. Self-oblivious, he was entirely concentrated upon nature and its mysteries, never resting till something of these should be revealed. Self-glorification never occurred to him and while

the doings of Pasteur were being made public property, Béchamp shut in his quiet laboratory, was immersed in discoveries, which were simply published later in scientific records without being heralded by self-advertisement.³

The medical doctor who wrote the forward of Béchamp's own volume, *The Blood and Its Third Anatomical Element*, points out that one of Pasteur's promoters was the Research Advancement Society in England, "an organization which exists for the purpose of popularizing experiments on animals. Pasteur discovered . . . that if one gets into the limelight and . . . [has enough] push [money and political power to] . . . back . . . him, his name can be immortalized."⁴

If Béchamp was such an obviously superior and educated scientist, why were so many ready to believe Pasteur? The answer—which unfortunately is as familiar to us now as it was then—is *image*. Pasteur was a much better public speaker than Béchamp. Pasteur's more imposing and impressive presence is a good illustration of the extent to which social status determines what becomes regarded as "science." Also, powerful economic interests, including the chemical companies, were making money from Pasteur's fables. So they continued to help suppress Béchamp's discoveries and work. By the time of Pasteur's death, the germ theory was firmly entrenched in people's consciousness, propelled by a momentum of its own.

Although Béchamp's discoveries and research seem extraordinary on one level, they were based on common sense because they explained so many apparent anomalies in medicine. In every living entity, the scientist discovered, exists a basic unit smaller than a cell—an autonomous, living, molecular structure he named *microzyma* from the Greek words meaning "small" and "ferment." Rather than being harmful, Béchamp wrote, microzymas "function as anatomical elements in the living and healthy organism; there they are the physiological and chemical agents of the transformations which take place during the process of nutrition."⁵ In other words, microzymas are responsible for building cell tissue. In fact, they provide many useful services *until the terrain of the body changes and the tissues begin to degenerate. At that point, the microzymas change form and function according to their new environment.*

Altered microzymas comprise approximately a dozen different families consisting either of bacteria, viruses, or fungi. However, there is a hierarchy of appearance and structure among these pathogens. A bacterium is considered to be the first pathogenic change in a diseased body, and a fungal form is the last. This order of emergence and hierarchy of sophistication may be one reason that bacterial infections are easier to eliminate than

fungus infections: the body is not as far along in its process of deterioration. (Note that the bacteria referred to here are pathogenic, and not the essential microorganisms such as *Acidophilus* and *Bifidus* that live in the intestinal tract and help us digest our food. However, beneficial intestinal flora thrive and proliferate only under conditions that favor our health. Our own health means their health.)

Pathogenic microzymas further ferment unhealthy tissue, disintegrating it into its more elemental components. Eventually, the microzymas catalyze the total destruction of an organism without being destroyed themselves. When there is no more tissue, they revert back to their harmless state. Béchamp demonstrated this process by conducting an experiment with a dead cat encased in natural limestone, and thus protected from exposure to the air. After several years, the cat was completely decomposed by bacteria, which returned to their microzyma state after they completed their scavenger job. This experiment was repeatable. One author succinctly describes this process:

The bacteria found in man and animals do not cause disease—they have the same function as those found in the soil, or in sewage, or elsewhere in Nature; they are there to rebuild dead or diseased tissues, or rework body wastes and it is well known that they will not or cannot attack healthy tissues [original emphasis].⁶

Body tissues are healthy when they receive the proper nutrients. If there are no assimilable nutrients available for an adequate period of time, cells starve. In this state of starvation, the cells lose their vitality and ability to function and they decompose into diseased tissue, unable to support growth. Once this occurs, the microzymas transmute and immediately perform their cleanup. Simply put, then, the function of pathogenic microbes is to break down bodily tissue that's already diseased.

The scavenger function of bacteria has complex ramifications. If these modified microzymas were only getting rid of debris, we humans could eat whatever we wanted and subject ourselves to all kinds of abuse without worrying about the consequences. We could binge on junk, see the body react by becoming toxified, and then blissfully sit back while the transmuted microzymas cleaned up the mess. The problem is, once the microzymas have transmuted into bacteria, viruses or fungi, *feeding* on unhealthy and fermented body tissue causes them to *excrete* unhealthy (mostly acidic) waste materials. *These pathogenic waste materials—which are poisonous—further contribute to a rising spiral of sickness.* Thus the phrase, “You are what you eat,” acquires new meaning.

HEALING THE TERRAIN

Illness usually arises from many complex factors, not solely from a harmful microbe invading the system. Even if these microbes are directly addressed, the bodily terrain on which they feed must still be corrected. This includes the elimination of waste—particularly important for those who are toxified and ill. However, increased energy is required for waste removal, and a sick person generally doesn't have any energy to spare. Also, these transmuted microzymas are *reproducing* at a brisk rate, usually faster than the immune cells can eliminate them.

Compounding the problem, a very ill person generally harbors fungi and molds. These organisms, which appear at the final stage of a microzyma's transmutation cycle, often cause the most damage. Highly sophisticated in structure and function, they usually exist in an acidic environment. Acids cause more fermentation, which in turn creates even more transmuted microzymas. The microzymas then excrete more acidic wastes, which ferment even more tissue, creating more acidity—and the vicious cycle begins all over again. This contributes to, as well as directly causes, degenerative disease.

People harboring pathogens usually have little or no interest in eating nutrient-rich vegetables or clean animal protein. Instead, they prefer sweets, refined starches and alcohol, all of which further unbalance the terrain. This craving for junk is largely due to the hunger pangs of the sugar-loving pathogens, which need this unbalanced diet to survive. Not surprisingly, the biochemical messages sent by the parasitic microbes—“Feed me junk!”—are often confused with the person's own hunger signals. No wonder people sometimes feel enslaved by their cravings and wonder if it's possible to get well!

The body's terrain so strongly influences susceptibility to illness that some holistic sources claim “the terrain is everything.” However, I don't believe that this is true in *every* case of illness. In less than half a century, genetically engineered and unnaturally mutated pathogens have emerged that are so virulent, they apparently alter the terrain in even healthy individuals. One example is the huge, corkscrew-shaped Lyme spirochete, which can bore into bone and cause intense physical pain and severe disabilities, even blindness. Also, as scientists have discovered, microorganisms produce *biofilm*—a hard, glue-like coating that protects and hides them from the body's immune cells. Healing, therefore, requires many approaches to reestablish the integrity of the terrain.

Now I want to address arguments that appear to refute Béchamp's claim that diseases are caused by unbalanced internal conditions. History proves that a substantial

decrease in hospital fatalities and an improvement in public health took place once physicians began washing their hands before performing surgery and dressing wounds. However, as Walene James explains, “when unclean or putrefying matter—conveyed by hands, dressings, or other means—contacts fresh wounds, it introduces morbid microzymas that alter the normal function of the inherent microzymas of the body.”⁷ This is not a mere repeat of Pasteur’s germ theory. The differences, though subtle, are important. According to Pasteur, all disease originates from outside attackers (germs) that penetrate an otherwise pristine and healthy system, with no internal systemic response other than the mobilization of immune cells to ward off the invaders. However, as Béchamp recognized, the body is never a passive observer of its circumstances: there is always a synergistic relationship between internal and external conditions.

Take the example of decreased illness after doctors began washing their hands in hospitals. When a doctor performs surgery with unwashed bloody hands that have previously touched someone else’s open wound, the new surgery subject becomes sick because *foreign material*, rather than a *pathogenic microbe* per se, has been introduced into the subject’s body. The phrase “foreign material” is key here. Human beings are not constructed to harbor life forms that are alien to their innate processes. James summarizes Béchamp’s findings:

There are functional differences in the microzymas of (1) the same organs and tissues of the same animal at different ages, (2) the blood and tissues of different species, and (3) the blood and tissues of different individuals of the same species. Because microzymas of different species are functionally different, each species has diseases peculiar to it. Certain diseases are not transmissible from one species to another and often not from one individual to another, even of the same species. Microzymas, then, are species and organ specific and even person and age specific.⁸

The specificity of microzymas to a given location explains how the introduction of foreign blood proteins (to use the above example) can make someone sick. “It is not the inoculated organisms which multiply,” Béchamp wrote, “but their presence and the liquid which saturates them *causes a change in the surrounding medium* [the person’s body] *which enables the normal microzymas to evolve in a diseased manner.*” [emphasis added]⁹

Put another way, the introduction of agents foreign to the body upsets the chemical balance of the inner terrain. These foreign agents can be chemical toxins, junk foods, or waste products from abnormal microzymas. Once the

body’s environment becomes unbalanced, the microzymas that regularly inhabit the system change in response to the altered chemistry. The foreign proteins do catalyze the change. However, *the malady itself is caused by the body’s own altered microzymas that have formed in response to the changed environment triggered by these outside agents.* At this point, the pathogenic microbes that are multiplying are not foreign substances, but the body’s own transmuted microzymas which—because they are reproducing and spewing their toxic waste into the system—perpetuate the cycle of ill health as long as the inner terrain is disturbed.

An infection catalyzed by external unsanitary conditions must be dealt with in the same manner as any other imbalance that involves the body’s own transmuted microzymas: detoxification from the poisons, paying attention to proper diet, getting more rest, and so on. We are not dealing with separate diseases here, only different manifestations of unbalanced conditions. Significantly, Béchamp recognized the function of fever as “the effort of the organism to rid itself of the products of an abnormal fermentation and disassimilation, while inducing a return of the diseased microzymas to the [original positive] physiological condition.”¹⁰ Pathogens cannot live beyond certain high temperatures, so the body finds a way to “cook” them by producing a fever.

Béchamp’s colleagues and the general public ridiculed his discoveries. James analyzes the barriers that prevented them from accepting what the scientist had proven in his laboratory. The germ theory, she writes,

fit neatly into the mechanistic theories of the universe that were popular in the nineteenth century. Second, it fit “human nature.” Man, apparently, ever ready to avoid responsibility and place causation outside himself, found an easy scapegoat in the bad little organisms that flew about and attacked him. After all, it wasn’t too long ago that evil spirits had been responsible for man’s ills. Third, it fit “commercial nature.” When we place causation outside ourselves, we create vast armies of attackers and defenders, assailants and protectors. In the case of disease causation, our protectors are such things as vaccines, drugs, X-rays, and the like, and their administrators, medical practitioners. The possibilities for commercial exploitation are endless. Is it any wonder that the “powers that be”—conservative, well-established scientific authorities—were behind Pasteur?¹¹

Mechanistic thinking, the avoiding of personal responsibility, and commercial exploitation are still the dominant paradigm today. It’s entrenched in what we might call “establishment medicine.”

BÉCHAMP'S SCIENTIFIC PROGENY

Had Béchamp been the only physician who observed these basic units of life that transform as the body changes, he might have passed into obscurity. But professionals from many different sectors of the scientific and medical communities subsequently agreed with his findings. What follows is only a small sample.

Rudolf Virchow

By the age of 25, 19th century Prussian Rudolf Virchow had become a doctor. The founder of pathology, he discovered and named many structures and tissues in the human body. Perceiving that the presence of harmful microbes was the effect—rather than the cause—of disease, he used the analogy that mosquitoes gravitate to stagnant water to feed, rather than being the cause of the stagnation itself.

Florence Nightingale

Florence Nightingale was a 19th century British mathematician and nurse who turned the devalued art of nursing into a respected profession and championed public sanitation because she understood that protecting the terrain was the biggest deterrent against pathogens. In 1860 she remarked:

Diseases are not individuals arranged in classes, like cats and dogs, but conditions growing out of one another. . . . I was brought up . . . to believe that smallpox . . . [began as] a first specimen in the world, which went on propagating itself, in a perpetual chain of descent. . . . Since then I have seen . . .

smallpox growing up in first specimens . . . where it could not by any possibility have been “caught.” . . . Wise and humane management of the patient is the best safeguard against infection—the greater part of nursing consists in preserving cleanliness. The specific disease doctrine is the grand refuge of weak, uncultured, unstable minds, such as now rule in the medical profession. *There are no specific diseases; there are specific disease conditions.*¹²

Guenther Enderlein

A little later, in Germany, scientist Guenther Enderlein (1872–1968) wrote about the different phases of the life cycles of microorganisms. He described how what he called *endobionts* climb the evolutionary ladder very quickly from their basic size of 0.01 microns and become larger, assuming more complex forms with the increased ability to perform complicated functions. In *Bakterien Cyclogenie (The Life Cycle of Bacteria)*, Enderlein pointed out that the highly varied forms these endobionts assume is a different phenomenon from the adaptive changes that occur when a bacterium becomes resistant to an antibiotic over several generations. He called pathogens *pleomorphic*, from the Greek meaning “many forms.” Echoing Béchamp, Enderlein emphasized that the numerous developmental stages of a microbe are not freaks of nature, but naturally occurring under certain conditions as part of the microbial life cycle. Pleomorphism, Enderlein wrote in 1950, “is easily affected . . . by increasing the local pH value.”¹³ (See Sidebar, “Antibiotics and Pathogen Behavior.”)

Enderlein had access to better microscopes than did Béchamp. Besides presenting specific data about how

Antibiotics and Pathogen Behavior

Many times after the administration of antibiotics, people either feel a need to take another cycle of the same drug—“because the medicine didn’t kill all the germs”—or they become sick with an apparently unrelated illness, to which they respond by taking a different drug. There are three reasons for the growing immunity of pathogens to antibiotics. One, if enough antibiotics are ingested over a period of time (either directly, or through the consumption of non-organic commercial meat, whose animals are routinely fed antibiotics), the pathogens will mutate into a more resistant form that is not necessarily part of their normal pleomorphic cycle. This scenario is now widely acknowledged as fact by the allopathic community, but they respond by creating even more deadly poisons to kill the strengthened pathogens instead of carefully limiting the use of antibiotics or stopping that use entirely.

Two, even if a pathogen is killed, another pathogen can be released from the first. For instance, viruses can live inside bacteria. So the host may still feel ill, even if the initial infection is eliminated.

The third reason that antibiotics don’t work is not readily understood by allopathic doctors and researchers. Even if a drug succeeds in eliminating a specific microorganism, that microorganism is one, narrow range of pathogen in an entire pleomorphic family. The drug has not eliminated other pleomorphic forms of the same pathogen, either higher up or lower down on the evolutionary chain. Unless the unhealthy terrain of the body is changed, the same symptoms may reappear in the future. Or, other forms in the same microbial family will cause new, different symptoms regarded as an unrelated, apparently different disease.

numerous classes of microorganisms function, he was able to describe their different shapes in some detail. He developed a comprehensive program of biological medications directed at the microbes' progressive life cycles to help the body eliminate the pathogenic forms and rebalance itself. Enderlein understood, however, that as long as the bodily terrain supports pathogens, they'll evolve into more toxic forms. That is why he also emphasized a healthy diet and the elimination of acidic wastes from the person's system as major components of good health.

Bruno Haefeli

Swiss biologist Bruno Haefeli worked with Enderlein. He reported that when acid accumulates in the body's cells due to poor diet and other stress, the cells begin to ferment. This provides a tasty snack for the malevolently transmuted microzymas and a wonderful opportunity for them to further ferment bodily tissue. Haefeli's name for the basic unit of microorganism was *protit*, but the concept was the same. All over the world, scientists were amassing the same data and responding with the same conclusions: Many kinds of generally benign microorganisms evolve into visually and functionally different, more harmful forms if conditions in the body support the change.

Wilhelm Reich

Around the time that Enderlein was working in Germany, and then later in Europe and the United States, his contemporary, natural scientist and psychiatrist Wilhelm Reich, followed a similar course (and geographic itinerary) with his own examination of microorganisms. In the 1930s, through special high-magnification microscopes that used dark field condenser technology and had a viewing capacity of up to 4500 times, Reich was able to examine the life processes of minuscule organisms. After extensive experiments, he discovered living, mutable microscopic entities that he called *bions*. "My observations [of these bions] and the resulting hypotheses," Reich freely acknowledged, "clashed severely with the 'germ theory.'"¹⁴ These bions appeared to be none other than Béchamp's microzymas and Haefeli's protits. Based on the fact that the blood of the cancer subjects he studied produced pathogens much more readily than did the blood of healthy people, Reich concluded that one's tendency to develop cancer was based on the inability of blood and tissue (the terrain) to resist putrefaction.

Significantly, Dr. Reich cautioned his critics against trying to duplicate his experiments without using identical measuring tools—a common mistake made by many scientists who try to replicate the work of other scientists. "*It is not really possible*" he wrote, "*to verify the findings unless the same optics are used* [original emphasis]."¹⁵ This is why Reich described in detail the manufacturers, models, and technology of the microscopes that he used in his lab to examine the living specimens.

Echoing Béchamp and foreshadowing some modern microscopists, Reich believed that what we call the cancer virus is actually a mutation of some of the body's own minute biological structures.

Edward Rosenow

Knowledge of a pathogen's pleomorphic cycle wasn't limited to native Europeans. In the United States, work was being done by Edward C. Rosenow, MD, who published over 450 medical papers and was an associate at the Mayo Clinic for decades. In a 1914 issue of *The Journal of Infectious Diseases*, Rosenow described taking a variety of bacterial strains from different diseased tissues and placing them in separate Petri dishes that all contained the same nutrient base. After a short period of time, when he examined the different dishes, he found no difference between them. All of the harmful microbes had transmuted into the same form! (Rosenow and his colleagues were

able to see this phenomenon almost 20 years later through Royal Rife's microscope. This will be discussed shortly.) When Rosenow later returned the altered microorganisms to their original diseased tissues, *their offspring assumed the original form and function of the parent microorganisms*. Rosenow's simple experiment has been successfully repeated by other scientists.

Nutritional biochemist A. Van Beveren writes:

Thus there is no "*streptococcus*" for the throat and "*pneumococcus*" for the lungs. They are the very same bacteria feeding on—and being modified by—the substance they are breaking down. This is pleomorphism and, while once ridiculed, [it] is now being reconsidered in light of improved microscopic techniques.¹⁶

In modern Germany, no fewer than eight textbooks on pleomorphism have been published.

ROYAL RAYMOND RIFE

A Renaissance Man

As we explore pleomorphism, a major repeating theme is the quality of the microscopes used by the researchers. Although the microscopes of Béchamp's time limited his ability to see the more intricate details of microzymas, he could certainly identify them by function and location. The scientists who followed him achieved much more comprehensive descriptions due to improved microscope technology. This brings us to Royal Raymond Rife.

A surviving copy of Royal Rife's birth certificate shows that he was born in Nebraska in 1888. However, Rife historian Charlene Boehm points out that this document was a *delayed* birth certificate, recorded in retrospect and based on notarized statements of people whose memories might be faulty. Various records show that the Rife family was actually living in southwest Iowa. Royal was raised by an aunt and uncle, as his mother died shortly after his birth and his father was unable to take care of him. In the early 1900s, Rife moved to San Diego and by 1912 he married a Chinese-American woman named Mamie Ah Quin.

Mamie, the third of twelve children, had been born into a wealthy and prominent family within the San Diego Chinese community. Her father was so well respected, in fact, that he was regarded as the unofficial mayor of Chinatown. Among his many accomplishments, the elder Ah Quin was a labor broker, recruiting newly arrived Chinese immigrants to build the railroad. He also had considerable bilingual talent and extensive legal knowledge, which made him a favorite translator in the courts. Documentation shows that Mamie's father was so eager to assimilate into American culture that he cut off his back braid—an offense punishable by death in China.

More is known about the Ah Quin men than the women. The men in the family were established entrepreneurs. For example, one of Mamie's brothers became part owner of a tourmaline mine that supplied jewels to the Dowager Empress in China. It has been reported that all of the Ah Quin children received musical instruction, so it's logical to assume that Mamie's upbringing focused on breeding, education, and adaptation to a new culture. All this, and her striking physical beauty, evidently attracted Rife to her. It was illegal for Caucasians to marry non-Caucasians at that time, so Rife and Mamie very likely got married across the border in Tijuana, Mexico—a reasonable guess, because when the youngest daughter Mabel married a Caucasian, documents show that she did this in Tijuana in the 1920s.

By 1920, Mamie and Royal had moved onto the estate of Amelia and Appleton Bridges, who hired Rife

as a chauffeur and car mechanic. The Bridges quickly recognized that Rife was not a typical employee. A gifted musician and artist, Rife had already educated himself in the fields of optics, electronics, biology, and chemistry. Additional education (whose documentation has not been substantiated) is believed to have included studies at Johns Hopkins University, training to perform eye surgery, and instruction with optical scientist Hans Luckel, who worked for German-based company Zeiss Optics and was in the New York plant when he presumably taught Rife. Popular literature says that Rife received an honorary Doctor of Parasitology degree from Heidelberg University, but the university has reported being unable to locate such a degree. Even without this honorary degree, though, Rife's intellect and accomplishments are impressive.

Throughout his life, Rife designed and built many medical research instruments. These included different types of spectroscopes (to split light into its constituent wavelengths), micromanipulators (tools that move, cut, or inject specimens under a microscope with great precision), a device to take stop-motion photomicrographs (pictures filmed through microscopes), and other optical tools. With one of his own photomicrograph inventions, he is thought to have made all of the pictures that appeared in the *Atlas of Parasites*, published by the University of Heidelberg in Germany. According to several reports, at some point the governments of the US and several foreign countries awarded Rife over a dozen medals for scientific work involving machine gun synchronization gears, variable pitch propellers, inclinometers (which measure the slope of an object), and high altitude barometric pressure scales.

Royal Rife reportedly had a period with the United States Navy during World War I when he traveled to Europe to examine foreign laboratories for the US government. Among other tributes, he was awarded a Research Fellowship in Bio-Chemistry by the Andean Anthropological Expedition Institute for Scientific Research on August 10, 1940. According to Rife researcher and engineer Dave Felt, Rife was offered an honorary Doctor of Science degree by the University of Southern California in 1936, but he did not accept it.

While still living on the Bridges estate, Rife conducted microscopic examinations on some samples of the metal used for ball bearings in a factory owned by Henry H. Timken, millionaire industrialist and the brother of Amelia Bridges. Rife discovered weaknesses in the grain structure of the metal and saved Timken money. Most of Rife's efforts, though, were devoted to his laboratory, which was located above the garage on the Bridges estate and was financed by Bridges and other wealthy sponsors, including Timken. It was in this lab that Rife created some remarkable optical equipment.

The Universal Microscope

Rife, accustomed to working alone, became a public figure when he began building microscopes that were far superior in resolution and performance to anything thus far available. Although Rife was a contemporary of both Enderlein and Reich, he appeared to be unaware of the microscope technology and research of his European counterparts. We do know, however, that he was so dissatisfied with the quality of microscopes in the US that he vowed to create something better.

The most powerful and celebrated instrument, completed in 1933, was the 200-pound, 5,682-part Universal Microscope. Standing between two and three feet high, it had a magnification power of about 60,000 times, with a resolution of 31,000. Rife's microscope had some unique design features. "The New Microscopes" by Raymond E. Seidel and M. Elizabeth Winter, which described how the Universal Microscope worked, appeared in a 1944 *Journal of the Franklin Institute* and was reprinted in the *Annual Report of the Board of Directors of the Smithsonian Institution* for the period ending June 30, 1944. (Rife later remarked that despite a few errors, the article was basically correct.) Some highly technical details from the article are included to illustrate the level of expertise and legitimacy conferred on Rife by the medical community.

Dr. Royal Raymond Rife of San Diego, California . . . has built and worked with light microscopes which far surpass the theoretical limitations of the ordinary variety of instrument. . . . The entire optical system of lenses and prisms as well as the illuminating units are made of block-crystal quartz The illuminating unit used for examining the filterable forms of disease organisms contains fourteen lenses and prisms. . . .

When light comes into contact with a polarizing prism, it is divided or split into two beams, one of which is refracted to such an extent that it is reflected to the side of the prism without, of course, passing through the prism while the second ray, bent considerably less, is thus enabled to pass through the prism to illuminate the specimen. When the quartz prisms on the universal microscope, which may be rotated with vernier control through 360°, are rotated in opposite directions, they serve to bend the transmitted beams of light at variable angles of incidence while, at the same time, a spectrum is projected up into the axis

Where the telescope ends, the microscope begins. Which of the two has the grander view?

(1802–1885)

of the microscope, or rather a small portion of a spectrum since only a part of a band of color is visible at any one time. However, it is possible to proceed in this way from one end of the spectrum to the other, going all the way from the infrared to the ultraviolet. *Now, when that portion of the spectrum is reached in which both the organism and the color band vibrate in exact accord, one with the other, a definite characteristic spectrum is emitted by the organism. . . .*

*A monochromatic beam of light, corresponding exactly to the frequency of the organism (for Dr. Rife has found that each disease organism responds to and has a definite and distinct wave length, a fact confirmed by British medical research workers) is then sent up through the specimen and the direct transmitted light, thus enabling the observer to view the organism stained in its true chemical color and revealing its own individual structure in a field which is brilliant with light. [emphasis added]*¹⁷

Rife's method of illuminating microscopic structures was extraordinary. Microorganisms seem invisible to us because the human eye can see only a very narrow band of light (color) on the electromagnetic spectrum—and not in the ultraviolet range that many microorganisms reflect. However, applying certain laws of optics, Rife translated the natural emanations of the microorganisms to the portion of the electromagnetic spectrum that humans can see. By rotating the microscope's quartz prisms in various configurations, Rife literally *tuned into the frequencies* of these tiny specimens, expressed as color on what, to us, is the visible light portion of the electromagnetic spectrum.

Put another way, as Rife approached the precise frequency of the microorganism, it began to resonate or oscillate in response to the narrow band of light that was being aimed at it. The microorganism became illuminated when the light that was shone on it matched its own inherent, energetic light wave signature. Typhoid presented itself as brilliant turquoise, the cancer virus as purplish-red, and so on. (See Sidebar, "Viewing the Carcinoma Virus.")

Even when magnifying specimens only 31,000 times (its lowest range), the Universal Microscope surpassed the best light microscopes that used conventional lighting (such as the popular Zeiss dark field, oil immersion scope). It also easily surpassed the electron microscope,

which was still being developed then. Even if the electron microscope did have better resolution during Rife's time, it still would not have been useful to the scientist. An electron microscope can enlarge an image up to one million times, but it does this by bombarding the slide with electrons in a vacuum—conditions under which no living organism can survive. If a pathogen has to be killed in order to be observed, vital information is lost, such as how it functions in its natural state, what encourages its growth, and what can harm or destroy it. World Research Foundation founder Steve Ross once pointed out during an interview that the practice of killing specimens before viewing them is “like picking up a dead dog in the street and trying to figure out what the personality is. . . . You're not looking at the same organism.”¹⁸

Rife's colleague, Dr. Rosenow, was impressed with the microscope's capabilities. “Examination under the Rife microscope of specimens containing objects visible with the ordinary microscope, leaves no doubt of the accurate visualization of objects or particulate matter by direct observation at the extremely high magnification obtained with this instrument.”¹⁹

With such high resolution, not only did the Universal Microscope allow tiny microorganisms to be viewed, it also proved that harmful microbes were pleomorphic. This was discussed in “The New Microscopes,” in which the authors named many microorganisms that became visible through Rife's optical instrument.

The human body itself is chemical in nature, being comprised of many chemical elements which provide the media upon which the wealth of bacteria normally present in the human system feed. These bacteria are able to reproduce. They, too, are composed of chemicals. *Therefore, if the media upon which they feed, in this instance the chemicals or some portion of the chemicals of the human body, become changed from the normal, it stands to reason that these same bacteria, or at least certain numbers of them, will also undergo a change chemically since they are now feeding upon media which are not normal to them*, perhaps being supplied with too much or too little of what they need to maintain a normal existence. They change, passing usually through several stages of growth, emerging finally as some entirely new entity—as different morphologically as are the caterpillar and the butterfly. . . . The majority of the viruses have been definitely revealed as living organisms, foreign organisms it is true, but which once were normal inhabitants of the human body. [emphasis added]²⁰

Rife himself understood the importance of pleomorphism. “It is not the bacteria themselves that produce the disease,” he emphasized, adding that he and his colleagues “believe it is the chemical constituents of these micro-organisms enacting upon the unbalanced cell metabolism of the human body that in actuality produce the disease. We also believe,” he acknowledged, “if the metabolism of the human body is perfectly balanced or poised, it is susceptible to no disease.”²¹

Fortunately for Rife, there were a number of highly respected doctors and researchers in the medical and scientific communities who supported his work. Before Rife's third Universal microscope was completed, he met bacteriologist Arthur I. Kendall. Kendall held many important positions during his lifetime, among them Dean of Northwestern Medical School, instructor at Harvard University Medical School, Director of the Hygienic Laboratory (the forerunner of the present National Institute of Health), and chair of the Department of Bacteriology at Northwestern University in Illinois. Like Dr. Rosenow before him, Dr. Kendall had independently investigated the pleomorphic character of pathogenic microbes. In a nutrient medium he developed (called the “K-medium”), he placed bacterial cultures that transmuted into another form. Once the delighted Kendall was able to view the transmuted bacteria through Rife's microscope and further confirm his findings, the two men began working together closely. Thereafter, Rife conducted many experiments with both Kendall and Rosenow, who both made public their position on pleomorphism. In the December 1931 issue of the journal of the California Medical Association, *California and Western Medicine*, Rife and Kendall published a report of some of their experiments on filterable forms of *Bacillus typhus*. Rife wrote:

We have classified the entire category of pathogenic bacteria into 10 individual groups. Any organism within its group can be readily

Viewing the Carcinoma Virus

Although Rife was usually successful in viewing microorganisms, initially he had trouble detecting the carcinoma virus. One day, he serendipitously placed a tube of cancer culture inside an electrified glass ring filled with argon gas and left it there for about 24 hours. When he later examined the culture through his microscope, he noticed that it had acquired a purplish-red color that now made it visible. Remarkably, the specimen was still living. Thus Rife discovered a method of “staining” the cancer virus with certain frequencies on the electromagnetic spectrum, and without killing it.

changed to any other organism within the 10 groups depending upon the media with which it is fed and grown. For example, with a pure culture of *bacillus coli*, by altering the media as little as two parts per million by volume, we can change that micro-organism in 36 hours to a *bacillus typhosis*. . . . Further controlled alterations of the media will end up with the virus of poliomyelitis or tuberculosis or cancer as desired, and then, if you please, alter the media again and change the microorganism back to a *bacillus coli*.²²

Rife also described the pleomorphic nature of the cancer virus.

By continued microscopic study and stop motion photographs, it was found that the “BX” virus had many changes and cycles as so with other micro-organisms.

The virus can be readily changed to other forms or cycles of themselves by the media upon which they are grown. By [making] the “K” media slightly acid, we no longer have a “BX” as we have classified this cancer virus, but we have what we term a “BY.” In this stage or form, it is still a virus, but considerably enlarged from the initial “BX.” Still retaining a purple red refractive index, but will no longer pass the porosity of the W porcelain or diatomaceous earth filter. In this stage, the “BY” requires a much coarser N filter.

The next stage finds this micro-organism, now known as the monococoid form, in the monocytes of the blood of over 90% of carcinomatous [sic] individuals.²³

It was important that the medical community learn about the growing documentation of pleomorphism, as well as the technology available to observe it. So on November 20, 1931, a distinguished doctor named Milbank Johnson gave a banquet in his Pasadena, California home to honor the accomplishments and achievements of two men: Dr. Kendall, for his K-medium in which pathogens could be grown, and Royal Rife, for the microscope that enabled pathogens to be viewed. Among over thirty guests were some of the most prominent medical doctors, bacteriologists, and pathologists in the country. According to Steve Ross, in addition to such live meetings, over one hundred newspaper articles were written about the Universal Microscope alone in the 1930s and 1940s. Pictures of some of the original newspaper articles appear in the photo essay spread in this chapter.

Additional documents from that period show that many eminent researchers enthusiastically endorsed and used

the microscopes that Rife built. In a more recent article on Rife, Gerry Vassilatos reports that Rife’s microscopes:

were immediately obtained by Northwestern University Medical School, the Mayo Foundation, the British Laboratory of Tropical Medicine, and other equally prestigious research groups. . . . [Many] specimens were obtained and studied. . . . Active poliomyelitis cultures were studied, the virus successfully isolated, identified, and photographed in 1932 by Rife and Kendall. In these cultures the team recognized streptococcus and motile blue forms resembling typhosis. These last reports were immediately transmitted to the Mayo Foundation and duplicated by Dr. E. Rosenow. Dr. Karl Meyer (Director of the Hooper Foundation for Medical Research, University of California) came to the Rife Research laboratories with Dr. Milbank Johnson, examining and corroborating the stated results. The impossible and anomalous became fact. Bacilli could act as virus carriers. Furthermore, poliomyelitis victims evidenced a startling degree of typhosis-like associated virus.²⁴

The discovery that viruses can exist inside bacteria (in the form of *bacteriophages*) is critical, and impacts on the treatment of disease and the success or failure of rifting. This will be discussed further in Chapters 4 and 5.

Rife was not content simply to view and identify microorganisms. He wanted to cure disease. If he could identify harmful microbes by using frequency, he reasoned, he could use frequency to destroy them.

Frequency is the number of cycles per second at which an object can vibrate, commonly expressed in hertz (Hz). Everything has an inherent *resonant frequency* or *oscillatory rate*. A competent architect is aware of this principle when designing bridges. If a bridge is built without its oscillatory rate factored into the construction, a hurricane or heavy wind could cause the bridge to steadily vibrate in harmonic resonance for a long enough period that parts of the bridge (if not the entire structure) would shatter or collapse. (See Sidebar, “Gallop Gerty: the MOR of a Bridge.”) Compromising the structural integrity of a bridge by exposing it to its oscillatory rate is similar to disabling or shattering a pathogen by exposing it to *its* oscillatory rate. Rife’s microscopes, whose high magnification abilities allowed him to see how live microorganisms reacted in their environment, were indispensable to his future accomplishments. He would use frequencies to destroy tiny microorganisms—and the instrument of destruction would be the Rife Ray.

The Rife Ray

It was in “The New Microscopes” article that readers also learned about “certain lethal frequencies”: the fields emitted by the Rife Ray, which Royal Rife created eleven years after the debut of his Universal Microscope.

Under the universal microscope . . . tuberculosis, cancer, sarcoma, streptococcus, typhoid, staphylococcus, leprosy, hoof and mouth disease, and others [pathogens] may be observed to succumb when exposed to certain lethal frequencies, coordinated with the particular frequencies peculiar to each individual organism, and directed upon them by rays covering a wide range of waves. By means of a camera attachment and a motion-picture camera not built into the instrument, many “still” micrographs as well as hundreds of feet of motion-picture film bear witness to the complete life cycles of numerous organisms.²⁵

Rife designed several styles of ray equipment. There are at least four numbers that historians have used to designate the machines, but it wasn’t clear when these units were begun or finished, or when they were formally used. We do know that the earliest one, built in the 1920s, killed *E. coli* (called *B. coli* then), a common bacterium that lives in the colon. Rife continued developing his ray equipment throughout the 1930s. In 1934, he built what some people today refer to as the Rife Ray #3. It was comprised of several bulky pieces that filled a large table in Rife’s laboratory, making it not only difficult to move but also labor intensive to calibrate and operate. To produce the frequencies, the Rife Ray #3 used a Kennedy brand off-the-shelf radio receiver, which Rife also used as a transmitter. The Kennedy brand receivers were *regenerative*, which simply means that they had built-in components designed to amplify the electronic signal so it would be stronger. However, as the Kennedy receivers were not *shielded* (more about this in a moment), other types were probably preferred in the final designs.

Frequencies were emitted from the glass ray tube, which was mounted on a base on the outside of the cabinet and connected to the receiver. The ray tube used for the Rife Ray was similar to X-ray machine tubes of the era. However, it didn’t produce X-rays because X-rays are created in a vacuum, and this ray tube contained an inert gas. Rife initially experimented with mixtures of different noble gases, including argon and krypton. He eventually chose helium because it withstood “many more hours of bombardment”²⁶ than the other gases he tried. The gas-filled tube became brightly lit when a frequency of sufficient power was passed through it.

Presumed to have been more powerful than its predecessors, the Rife Ray #3 outputted about 50 watts to the tube. Fifty watts was enough power so that the frequencies emitted by the tube could penetrate through 15 inches of concrete. Even when the Rife Ray was one floor away from where the microscope stood, Rife demonstrated that after about ten minutes, every specimen beneath his microscope died after the machine was turned on briefly. The pathogens were devitalized not by the visible light emitted by the tube, but by the *electromagnetic field*, which includes electric and magnetic waves. Other bandwidth energies contributing to this effect may have included infrared and *scalar waves* (discussed in more detail shortly). Modern researchers sometimes refer to these combined fields as the “Rife effect.” The range of frequencies that Rife generally used were 190 KHz (kilohertz) to 12 MHz (megahertz).

Some components of the radio equipment included vacuum tubes. Housed inside the cabinet, the vacuum tubes were entirely different from the ray tube that was mounted on the outside of the cabinet. Vacuum tubes were somewhat fragile and bulky, used a lot of energy, and overheated easily. That is why engineers developed the transistor in the late 1940s. Unlike a hollow tube, the transistor was solid (hence the phrase, “solid state technology”). Transistors possessed all the beneficial electrical properties of vacuum tubes without any of their shortcomings. They were sturdy, inexpensive and tiny, used very little power, and could immediately turn on without requiring any warm-up time. Today, virtually all electronic apparatuses (including electromedical devices) use solid state technology instead of vacuum tubes.

Galloping Gerty: the MOR of a Bridge

The Tacoma Narrows suspension bridge in the northwestern United States—now better known as “Galloping Gerty”—is quite famous because of the spectacular manner in which the structurally defective bridge collapsed over seven decades ago. The destruction happened to be captured on motion picture film, clips of which can be seen on the Internet. In 1940, the mile-long (1.6 kilometer) bridge shattered when a steady wind provided so much energy that the bridge began shaking. When the oscillations became intense enough, the entire bridge collapsed.

The shattering of the bridge provides an excellent analogy to the Mortal Oscillatory Rate of various pathogens, which Royal Rife discovered in order to disable or outright destroy them. It took ten years before the replacement to the bridge was completed. Correctly targeted microorganisms aren’t as lucky.

Rife is an expert in more lines than the average man has time to dabble in. He is an able bacteriologist, embryologist, electrical and scientific engineer, metallurgist, chemist, photo-micrographer, and he plays with scientific crime detection. As recreation he takes to target shooting in terms of half-inch bullseyes.

His chief enthusiasm, however, is the inquiry into the causes, agencies and forms of diseases, and it is this enthusiasm that has caused him to develop his various pieces of apparatus, and to refine them to an efficiency beyond all precedent.

San Diegan's Super-Microscope Gives First View Of Filtered Bacteria

Instrument Praised As
New Aid To
Science

PASADENA, Dec. 4. — Using the new "super-microscope" invented by Dr. Royal Raymond Rife of San Diego, Dr. Arthur Isaac Kendall of Northwestern University Medical School has seen for the first time the exceedingly minute moving bodies that apparently carry the life of bacteria when these are induced to "dissolve" into a form that will pass through the pores of the finest porcelain filter and still remain alive.

The work was done at the Pasadena hospital, and will be reported in the official publication of the California Medical Association, California and Western Medicine.

Bacillus Used

The material used by Dr. Kendall was a culture of the typhoid bacillus, ordinarily a fairly large germ, easily visible under the higher-powered lenses of a compound microscope. By feeding it on his recently-evolved "EC medium," which apparently has the power of causing all visible bacteria to pass over into an invisible, filterable phase, Dr. Kendall induced the bacilli to go through this change. Under the highest power of the ordinary microscope, he could see nothing moving in the fluid, except a swarm of rather active little granules that could be seen only as tiny motile points.

Examination with the Rife microscope, however, these points became plainly visible as small, oval, actively moving bodies, turquoise blue in color. These appeared in all the cultures, and could be transferred from one culture to another through the fine-

A new superpower microscope which magnifies objects to 5000 times their normal size has been perfected here by Dr. Royal Raymond Rife, shown above with his invention. Six quartz lenses are used in the powerful new instrument, which magnifies on a scale which would make an ant appear larger than an elephant. Another unusual thing about the microscope is that objects seen through it are shown in true perspective, rather than in reverse focus, as is the case with previous microscopes.

pored filters: so Dr. Kendall considers them to be the actual filterable form of the typhoid bacillus.

Microscope Praised
This visual demonstration of the hitherto invisible, living and moving particles of the filterable phase of a bacillus, is hailed editorially by California and western medicine. Of Dr. Rife's microscope, the editorial says:

"Whereas our present microscopes magnify from one to two thousand diameters, in this new

microscope we have an instrument for which a magnification as high as 17,000 diameters is claimed.

"This is certainly a long stride from the initial efforts of Van Leeuwenhoek, whose simple instrument may be said to have laid the foundation for the science of bacteriology which later came into being; and by means of which science much of the world's progress in man's conquest of the infectious and other diseases has been made possible."

As with all electronic equipment, Rife's frequency devices were potentially vulnerable to being affected by unwanted stray electromagnetic interference. The interference could come from motors, generators, cables carrying high levels of alternating or direct current, transformers, and even the Earth's own magnetic field. For a unit such as the Rife Ray—which required precision calibration and relied on exact frequencies to disable pathogens—even a little bit of interference could make a huge difference in whether or not the device was effective. Therefore, it was curious that with at least one of the Rife Ray models, the components were not adequately protected from stray magnetic fields.

This unwelcome variation in frequency would not have occurred had the equipment been shielded—a problem with just about any electronic device that was widely recognized even during Rife's era. *Shielding* is the use of various materials to surround and protect components so they can operate properly without interference. Any material that's conductive can be used to shield sensitive components. The material diverts the interference field so the field travels *around* the device instead of *through* it. The shielding can be used to either *keep out* the field, or *confine* the field so it doesn't disturb other equipment that's in the same room, next door, or miles away. Shielding materials include wire mesh, metal enclosures, conductive paint, foil tape, adhesive compounds, and mu-metal. Mu, made from nickel, iron, copper and molybdenum, very effectively protects against static fields and low frequency magnetic fields. Mu-metal was available in Rife's time, but it was (and still is) quite expensive. Today, to avoid interference, it's customary to shield sensitive equipment—everything from high definition cathode ray tubes to amplifier circuits to wiring. This shielding, which is internal, usually consists of small enclosures made of metal or some other material, placed around selected components inside the equipment. Occasionally, for further protection, external shielding that surrounds an entire device is used. However, this is employed mainly by electronics professionals.

I discuss shielding in some detail because it's relevant to modern equipment. Most of the shielding problems in contemporary machines involve interference with external electronics. Any good frequency device costing thousands of dollars should be shielded. An unshielded unit running in the same room as a working computer or television will create a wavy picture, static, or both. Interference can also occur during rifting, when the unit's power output

augments a signal from an amplifier—resulting in an annoying hum that many people report hearing in their television set or their phone line. Moving the frequency instrument away from the other electronics usually eliminates the hum. If sharing the same wall sockets or circuits causes interference, the problem can be corrected by using different fuses or circuit breakers.

The frequency capability of Rife's equipment spanned from what engineers call the *audio range* on the electromagnetic spectrum (measured in hertz, abbreviated Hz) to the *ultrasonic* and *broadcast* ranges (measured in megahertz, abbreviated MHz). The term “audio range” can be confusing. It simply refers to a frequency that *could* be heard *if* the electromagnetic waves were converted into sound waves. MHz frequencies (much higher, in the millions of Hz), if convertible to sound waves, would be beyond the range of human hearing; so they aren't considered to be in the “audio” range.

In some of his units, Rife used a radio frequency (RF) *carrier wave*, which was always in the MHz range. The RF signal served a dual purpose. The high-frequency signal was necessary to light the tube. But it also served as a foundation upon which other frequencies could ride it, like a ship on the ocean (the RF) carrying passengers (frequencies). Using a carrier wave with a frequency produces *heterodyning*—the combining and merging of the two, which in turn creates more new frequencies. The new frequencies result from both the sum of the originals and the differences between the originals. With Rife's units, it was sometimes impossible to determine which frequency was doing what, as all the signals sent to the ray tube were important. It was very likely the unique combination of frequencies, the wave shape, and the energy fields that did the healing.

The shape of the RF signal that was sent through the ray tube was a *sine wave*—which is symmetrical and has a smooth rounded shape. (*Square waves*, commonly used in modern equipment, could not be produced by the older units.) The ray tube distorted the waveform, which produced many *harmonics*—higher frequencies, weaker in power, created by a main frequency under certain conditions. Some of these additional, higher-frequency harmonics were even higher than what the receiver alone was capable of outputting. This helped make Rife's technology even more successful. (See Chapter 4 for more information about wave shapes and their effects.)

The ray tube was a partially directional *transmitter*. Because its power was concentrated into a small area, the

Scalar Wave Properties

Electromagnetic (EM) waves and scalar waves are different. An EM field can be separated into distinct electrical and magnetic fields that are *transverse*, or transmit at right angles from their point of origin. Scalar waves—also known as *longitudinal waves*—are parallel to their point of origin. EM waves have a beginning, middle and end, with correspondingly uneven amounts of strength. Scalar waves are *standing*, with uniform amounts of strength. One common catalyst for the release of scalar waves is their *coupling*, or engaging, with an EM field. EM fields can be generated not only by electronic devices, but also by humans. Research by Dr. Valerie Hunt focuses on human healers who emit not only EM waves, but also scalar waves.

“The concept of scalar waves,” writes British physicist Noel Huntley, “is beyond the scope of conventional science, but not quantum physics. The data on scalar waves from Maxwell’s brilliant, original electromagnetic equations was removed prior to publication.”²⁷ Scalar waves are difficult to detect using standard equipment, as they do not register on an oscilloscope. Remarkably, though, conventionally trained engineers cite their incomplete education, inadequate measuring devices, and limited experience as proof that scalar waves do not exist. This is similar to some professionals who looked through Royal Rife’s microscope and did not see various pleomorphic strains of the same microorganism because of *their* preconceptions.

Certain plasma tube units are uniquely suited to emitting scalar waves. The noble gas inside the tube is excited, the electrons of atoms are hurled into a higher orbit, and the chaotic-wave gas turns into higher-energy, coherent-wave plasma (which moves in a spiral), known as the “fourth state of matter.” Once the catalyst that caused this higher-energy state is withdrawn, the plasma collapses back into gas. In order for this collapse to occur, the plasma must release energy, one form of which consists of photons of light. The rapid move back and forth between states (gas to plasma to gas to plasma, etc.) is probably what initiates the production of scalar waves. Such waves are then received directly by certain cell structures that process and power metabolic functions. We can perceive scalar waves due to their effects: the restoration of biological tissue, and the proper function of living organisms.

practitioner placed the tube either within a few inches of the subject’s body or, in some cases, directly on the person. Dr. Robert P. Stafford, a colleague of Rife, reported that when he treated people who had cancer, he focused on six square inches at a time, slowly moving the tube so that eventually it covered the entire affected area of the body.

The Rife Ray’s ability to eliminate pathogens was based on Rife’s finding each organism’s MOR, or Mortal Oscillatory Rate, and dialing those frequencies into the machine. The May 6, 1938 edition of the *San Diego Evening Tribune* carried a now-famous article by Newell Jones explaining how the microorganisms died, through a process called *entrainment*.

Each organism requires a different wavelength. . . . [An analogy is] something similar to . . . when one musical tuning fork is set in vibration by sound waves emanating from another fork struck nearby. Another example is the vibration which almost everyone has noticed a pipe-organ note causes in windows or furniture of the room where the instrument is being played. Again, a similar thing happens when a radio cabinet rattles from sounds passing from its speakers.

It is commonly known that the sound from the first object causes the second to vibrate in harmony. . . . The thing where the original sound-

producing vibration occurs has the same pitch, wave length, [and] frequency . . . as the one giving the sympathetic response. . . . [One object may] have a frequency which only is a part of a complex frequency possessed by the other; that is, one may be a simpler tone which is one element in a complex tone characterizing the other.²⁸

The destruction of a microorganism has also been compared to the cliché of a soprano singing a pure, focused tone that shatters a glass whose resonant frequency matches that particular tone. While this glass-shattering phenomenon is real, the analogy of sound to describe how Rife’s equipment worked is technically incorrect. A sound wave is a mechanical motion. Rife’s units could affect microorganisms through many inches of concrete, which can absorb mechanical motion (and thus prevent it from being transferred elsewhere). Therefore, something else was responsible for the destruction of pathogens: *electroporation*, the abnormal permeability of either a microbial cell wall or a human or animal cell membrane. The permeability is most pronounced during an energy transfer, or *when there’s a match in wavelength* (frequency). The Rife Ray—through *resonance*, or the matching of wavelengths—transferred energy to a microbe’s cell wall. This increase in energy disturbed the electrical charge of the pathogen, causing a *change in shape and pattern*,

which compromised its structural integrity. Due to this electroporation, a pathogen would begin to destabilize.

Today, we understand one more probable manifestation of Rife's technology: *scalar waves*. Scalar waves are not part of the electromagnetic (EM) spectrum. A few innovative researchers have proposed that some modern plasma units emit scalar waves (as Royal Rife's instrument apparently did as well)—and that these scalar waves help regenerate the body as well as possibly devitalize pathogens. See Sidebar, page 215, "Scalar Wave Properties."

When Rife finally did find the MOR, explains chiropractor James Bare (who holds the patent on the Bare-Rife frequency machine), the microorganism "would lose its color and become clear as it absorbed the resonant energy [of the frequency] and changed or died."²⁹ Sometimes the pathogens shattered. Other times, they simply weakened and lost their motility (the ability to move spontaneously and actively). Jones explained that some pathogens "writhe as if in agony and finally gather together in deathly moving clusters."³⁰ "Some types," Rife himself stated, "will explode or disintegrate and some will gather together like log jams or agglutinate."³¹

All of Rife's frequencies were specific to the organism. They had to be accurate. The inventor stated, "One tenth of one meter [or a smaller denomination] off and you have nothing. . . . [The frequency must] be absolutely correct for that individual organism."³² (When Rife mentioned meters, he was referring to the *length of the wave* that corresponded to the actual frequency in Hz.)

How did Royal Rife determine the MOR of a pathogen? First he examined thousands of specimens and tissue cultures from laboratory animals and humans through the Universal Microscope. As usual, the microorganism was illuminated in its own colored light while the surrounding field remained white. Then Rife tested the samples to ensure that a specific disease correlated to a specific pathogen, using the allopathic medical model of Koch's cause-of-disease hypothesis. Finally, Rife would turn the dials of the Rife Ray ever so slightly, switch on the power, and then examine the slide under the microscope to see if this time he had found the correct frequency.

The entire process was tedious, repetitious, and solitary. However, Rife was used to working this way. He had used the same painstaking observational skills years earlier when he tuned the microscope, bathing pathogens in their own light so he could view them. His colleagues described him as a man of immense patience. "I've seen Roy sit in that doggone seat without moving, watching the changes in the frequency, watching when the time would come when the virus in the slide would be destroyed," said Benjamin Cullen, who watched the scientist regularly.

Twenty-four hours was nothing for him. Forty-eight hours. He had done it many times. Sit there without moving. He wouldn't touch anything except a little water. His nerves were just like cold steel. He never moved. His hands never quivered.

Of course he would train beforehand and go through a very careful workout afterward to build himself up again. But that is what I would call one of the most magnificent sights of human control and endurance I'd ever seen.³³

As far as we know, Rife's technology did not harm the human or animal host. The oscillatory rates of humans and small mammals are much different from, and more complex than, the MORs of microscopic viruses, bacteria, and fungi. Rife was confident about the safety of his equipment, he stated on numerous occasions.

With the power that is in these [ray tubes], there is absolutely no harm. . . . I had my [ray] tube right here . . . about 11 or 12 inches away from the slide in the microscope. And here I was with . . . that tube going . . . year after year . . . and it never harmed me any.³⁴

And:

I stood in front of that thing [his ray tube] for 30 years finding these different frequencies that devitalize these different bacteria. And that thing was shooting on me right here [his chest], but it is absolutely harmless to normal tissue.³⁵

The non-invasive nature of this new method, plus the promise that it held, began generating great excitement in the medical community. Now they needed more.

Case Studies

By the end of 1932, Rife was destroying the typhus bacteria and numerous viruses (including the ones for cancer) that were grown in cultures and inoculated into lab animals. His equipment was able to destroy these pathogens whether they were in Petri dishes or in living animals. Then, as now, standard scientific protocol for testing drugs and other medical treatments involved using two groups of infected animals: the group that received treatment, and the control group that did not. If significantly more animals in the treated group lived than did those in the control group, this presumably indicated that the treatment was effective.

To prove the effectiveness of the Rife Ray, Rife was obliged to follow standard medical procedure. He injected

his rats with the disease organisms. Then he withheld treatment from the control group (all of whom died), and gave treatments to the other rats (all of whom lived). Within the confines of scientific protocol, Rife was kind to the animals. To spare them pain (which also made them easier to handle), he administered anesthesia before giving them injections or doing surgery.

Rife described the scientific protocol in detail:

On one series of cancer tests, I inoculated the virus which I had isolated and filtered from an un ulcerated breast mass into an albino rat. The tumor was allowed to grow and then I surgically removed the tumor and again isolated and filtered the virus from a portion of the ground up tumor and inoculated the next rat and repeated this procedure 411 times to prove that this virus was the causative agent of cancer.³⁶

Eventually, Rife had to prove that pathogens could be destroyed in humans without harming the host. To secure human subjects for his case studies, he sought the assistance of Dr. Milbank Johnson.

Johnson was the physician who had hosted the historic dinner honoring Kendall and Rife after the Universal Microscope was completed. He was enormously wealthy, with assets reportedly worth around \$15 million. After receiving a Doctorate from Northwestern Medical School in 1893, Johnson was awarded a Doctor of Law degree in 1916 from the University of Southern California, and another degree in 1920 from Northwestern University. The medically-related posts he held during his illustrious career included Professor of Physiology and Clinical Medicine at the University of Southern California; Chairman of the Claims Committee of the Pacific Mutual Life Insurance Company in 1920 and Claims Director of that company for most of the years from 1906 until 1936 (his retirement); member of the board of directors at California's Pasadena General Hospital; Chief Surgeon of the Southern California Edison company; and member of the Los Angeles Board of Health.

Johnson's humanitarian nature and his determination to eliminate illness are amply demonstrated in his surviving letters. The fact that his first wife died in 1920 of cancer, along with a *Streptococcus* infection following radiation treatments, undoubtedly made him even more interested in Rife's clinics. It was Dr. Johnson who convinced Timken to help finance Rife's new laboratory, which was built around 1936. Generally, Johnson remained loyal

and supportive to Rife for as long as the two men were in contact. Pivotal to all phases of Rife's career, Johnson advised and guided Rife. He generated publicity. And he helped Rife with projects.

Johnson himself initiated most (if not all) of Rife's clinical studies because Rife disliked the spotlight and preferred to focus on his laboratory research. To work with Rife, the doctor assembled some of the most prominent professionals with outstanding credentials (most of them had MD, PhD, or DDS degrees) from Canada, England, and the United States. These professionals did independent studies, performed laboratory research, and used the Rife Ray with paying clients as well. To test Rife's equipment on people with cancer and other illnesses, three clinics were set up, all of them funded by Johnson.

The first clinic, established in 1934, was at the La Jolla home of Ellen Scripps under the auspices of a University of Southern California "Special Medical Research Committee." Rife referred to this committee later on a legal document, and this particular clinic is often cited as a success by proponents of the technology. However, Rife researcher Dave Felt, based on a surviving letter by Dr. Johnson, believes that this committee was unofficial and the university's name was used "in order to have some liability

coverage for Scripps because they were using her property. Johnson probably asked Dr. Rufus B. von KleinSmid, president of USC, if he could form the clinic under the umbrella of the university, and Von KleinSmid said yes."³⁷

Most of Milbank Johnson's letters have been recovered. However, those dated between June 1934 and early 1935 are missing, so we can only guess at what actually occurred. From Dr. Johnson's surviving letters, we learn that he had no help and no assistants, and that Rife's involvement in the 1934 clinic was minimal. In fact, Johnson had to plead with Rife—in many ways the quintessential scientist who secludes himself in his lab—to get involved with the clinic. We know that between a dozen and 16 people were treated, most of them for cancer and a few for tuberculosis.

Of those in the 1934 study who were treated for cancer, some apparently did go into remission, because tissue and fluid samples sent to pathologist Alvin Foord at the Pasadena General Hospital were stated to be free of any traces of cancer. However, Johnson did report later that one man returned to him in the early part of 1935. The cancer in his cheek had not improved, so Johnson sent him to a hospital to have the corresponding eye, along with the malignant tissue behind the eye, surgically removed.

—Chinese proverb

In a December 1935 letter Johnson wrote to Dr. Mildred Schram of the International Cancer Research Foundation in Philadelphia—Johnson was apparently trying to solicit her assistance—he stated, “I am also going to give you a brief of the cases which I treated in La Jolla [the] summer before last with their present status in so far as I can find the patients. There was nothing done at that time of a conclusive nature.”³⁸

If results of the first trial were not exactly “conclusive” in the stellar way that all the participants had wanted, subsequent trials were more promising. The second clinic established by Johnson was at the Santa Fe Hospital in Los Angeles. It opened the first week of November 1935. As with the first clinic, it was Dr. Johnson who ran the Rife Ray.

The third clinic opened September 1936 at the Pasadena Home for the Aged, another Scripps facility. This study, which focused on cataract reduction and elimination, yielded impressive results: Dr. Johnson reported complete restoration of vision in 30 of 31 people he treated. The Pasadena clinic remained open until May 1937. Unfortunately for us, the frequencies used to eliminate the cataracts are not mentioned in Johnson’s report.

The equipment used in the 1936 clinic is thought to have been the Rife Ray #4. Johnson, eager to get the machine into clinics, enticed an electronics engineer named Philip Hoyland to do some part-time work for Rife. Hoyland built a compact, portable unit that could perform as well as Rife’s best prototype. It was highly successful. As Rife researcher Shawn Montgomery describes it, “The thing was a *bona fide* cure-all, provided you tuned it to the correct prescribed pathogenic frequency using a precise methodology. This was 1935 to 1936.”³⁹

Around this time, Rife also set up a new laboratory in Point Loma with the generous financial assistance of Henry Timkin. Some of the people who worked with Rife in the lab, participated in clinical trials, or administered the Rife Ray to their own clientele, were among the most respected professionals in the country. I mention the following people by name, along with some of their affiliations, to give a sense of the proficiency, talent, and enthusiasm that surrounded Rife and his work: Agnes Bering (who is believed to have worked with Rife in his laboratory from 1915 to 1946); T.O. Burger, MD; E.F.F. Copp, MD; James B. Couche, MD (pharmacist, physician and surgeon); Ben Cullen; George Dock, MD (Professor

Nikola Tesla, Albert Abrams, and Georges Lakhovsky: All Invented Forerunners of Rife’s Ray Machine

The inventions of three exceptional scientists in the field of electromedicine either directly contributed to or undoubtedly influenced Royal Rife’s own creation, the Rife Ray. The three were Serbian Nikola Tesla (1856–1943), Russian Georges Lakhovsky (1869–1942), and American Albert Abrams (1863–1924).

Around 1891, Tesla produced the Tesla Coil. It produced high-voltage, low-current, AC electricity that could run high frequencies. This may have given Rife the idea for part of the construction of the Rife Ray. Three years later, on February 6, 1894, Tesla was issued US Patent 0,514,170 for a plasma lamp. (Plasma is a fourth state of matter, formed when certain gases are extremely excited by high voltage.) Rife utilized a plasma tube to deliver the frequencies for his Ray device, so it’s difficult to imagine that he could have disabled harmful microbes without Tesla’s prior contribution.

In 1903, Georges Lakhovsky had postulated a theory (which was later proven) that all living cells—including microorganisms that cause disease—can act as both an emitter and receiver of very high frequency oscillations. We know today that cells do in fact conduct all kinds of waves: radio waves, microwaves, infrared waves and biophotons, not to mention electricity. Lakhovsky invented the very effective Multi-Wave Oscillator to energize cells and restore the function in living systems. Descendents of his technology, as well as copies of the original device, are still being used today. Royal Rife must have understood that his Rife Ray had a “secondary” effect of charging the body’s cells along with its stated goal, that of destroying harmful microbes.

Albert Abrams, a medical doctor born in San Francisco, California, invented the Oscilloclast in 1918. To eliminate disease, Abrams taught, it was necessary to deal with the electronic structures of atoms. He discovered that disease produces changes in the rate and manner of rotation of the electrons in atoms of affected tissue. If the electrons are not vibrating normally, the entire organism will be out of balance. Furthermore, he stated, *each disease has its own vibratory rate, affecting the motion of electrons in a unique way*. Abrams was able to analyze a single drop of blood, using sound and electronics, to determine the disease that was afflicting an individual. It’s difficult to believe that Rife didn’t know about Abrams. They both lived in California, where Rife could have heard about Abrams’s theory of disease and been inspired by the idea of finding the Mortal Oscillatory Rate for pathogens.

Like Rife, Abrams and Lakhovsky were denounced as quacks. Tesla was given some recognition, but some of his inventions and papers were stolen and he died penniless, without emotional support or recognition. Fortunately, the groundbreaking technologies of all these visionaries, along with Royal Rife, are now being recognized—and used.

of Medicine at Tulane University and later President of the Las Encinas Sanitarium of Pasadena, California); C. Fischer, MD (of the Children's Hospital in New York); Alvin G. Foord, MD (pathologist at Pasadena General Hospital and one-time president of the American Society of Pathologists); Oscar C. Gruner, MD (pathologist of the Archibald Cancer Research Committee at McGill University in Canada); Richard T. Hamer, MD; Joseph Heitger, MD (an eye doctor and good friend of Johnson); Arthur I. Kendall, PhD (inventor of the K-medium and observer of pleomorphism in pathogens); his daughter Alice Kendall (who assisted Rife in the lab); Royal Lee, PhD (inventor of spectrographic and other equipment, and the developer of whole food supplements that are still produced today by the company he founded); Ray Lounsberry, MD; Karl Meyer, MD (pathologist and Director of the Hooper Foundation for Medical Research of the University of California in San Francisco); Waylen Morrison, MD (Chief Surgeon for the Santa Fe Railway); Edward C. Rosenow, MD, ScD, and LLD (who had observed pleomorphism and was on the Mayo Clinic staff); Henry Siner (trained in microscopy by Rife and sent to England to demonstrate a virus microscope); Verne Thompson, electronics expert; Jack Free (Rife's primary lab technician); Ernest Lynwood Walker, BAS, ScD; and Arthur W. Yale, MD (Director of the Yale Foundation in San Diego). In addition, Charles P. Steinmetz from General Electric furnished Rife with hundreds of tubes, manufactured precisely to Rife's specifications.

Meanwhile, across America and in Europe, other doctors were administering Rife's therapy in their own offices. Numerous pathogenic microorganisms were being deactivated or killed outright. Among them were *Bacillus anthracis*, *Escherichia coli* (or *E. coli*, called *Bacillus coli* or *B. coli* in those days), *Staphylococcus*, *Streptococcus*, and *Treponema pallidum*. People recovered from sarcoma, carcinoma, leprosy, tuberculosis, typhoid, tetanus, gonorrhea, pneumonia, and other ailments. "I saw cancer and tuberculosis cases that had completely recovered," Rife wrote.

I saw Dr. Couche's brother who had come over from England. He had a 30 year sinus condition with terrible drainage. Dr. Couche used the

frequency instrument on him and he was well in three weeks. Dr. Couche had treated Dr. Hamer, MD for a sinus condition which cleared up. Dr. Couche had treated Dr. Butterfield, MD's brother-in-law who had a stiff wrist—a tuberculosis of the bone which cleared up. Also I saw a Mexican boy who had osteomyelitis of the bone which Dr. Couche cleared up with the frequency instrument. I saw George Lemm being treated by Dr. Couche for tuberculosis and he had come out from Chicago to die. He was sent from the Vulclain home. As soon as they found

out that Couche was getting results, they tried to get all of their patients back but Lemm said no, that he was going to finish up with Couche and he completely recovered.⁴⁰

Rife noted that two frequencies instead of one were needed to eliminate all the symptoms of tuberculosis because more than one pleomorphic form of the harmful microbe was involved in the disease. For cancer, Rife and his associates learned that treatment should be given for three minutes once every three days to give the

lymphatic system enough time to remove the toxins. (Modern frequency devices are different from Rife's original units, so treatment times are longer, and breaks between sessions are rare. For cancer protocols using contemporary equipment, see Chapter 5.)

According to Gary Wade, it was possible for the Rife Ray to have destroyed an entire cancer tumor in a single treatment consisting of one to one-and-a-half hours; but the resulting amount of dead tissue would have become "a feast for a massive bacterial infection" that "could lead to liver and kidney damage and general toxemia." In the three-minute treatments that were administered over a longer period of time, the Rife Ray killed "a thin outer layer of cancer tumor tissue at one time," thus allowing "the body's immune system to remove this layer before the next treatment."⁴¹ The administering doctors emphasized the need to drink two quarts or more of water a day—otherwise, the liver, kidneys and other organs would become overloaded from trying to eliminate, too fast, too many dead pathogens and their waste products. The production of waste did not worry the doctors: they understood it to be a normal outcome of detoxification. Because the Rife Ray didn't do anything except what it

It is really quite amazing by what margins competent but conservative scientists and engineers can miss the mark, when they start with the preconceived idea that what they are investigating is impossible. When this happens, the most well-informed men become blinded by their prejudices and are unable to see what lies directly ahead of them.

was designed for—the devitalization or destruction of pathogens—it could not be said to cause “side” effects as the phrase is commonly meant. The body’s reaction was a natural, reasonable, and in fact hoped-for process that occurs when corpses of harmful microbes and their waste products are being eliminated.

The years 1936 through 1939 were tumultuous. The Beam Rays Corporation was formed to manufacture more units, with both Rife and engineer Philip Hoyland listed as co-owners of the company. (Incredibly, Hoyland was given 55% ownership, leaving Rife with only 45%—a grievous error that Rife would later regret.) In May of 1938, a Hoyland-built compact unit (which used an RF carrier wave) was featured in lengthy articles appearing in the San Diego *Evening Tribune*. It is believed that Dr. Hamer was the first doctor to use this Beam Rays device in his clinic in the spring of 1938, followed by Dr. Couche (who had also used the #4 machine in the years preceding the Beam Ray model). Those lucky enough to have their health completely restored sent Rife sworn documents, some of which are posted at www.rife.org.

Royal Rife, as well as his investors, co-workers, friends and colleagues, hoped that this unit would help Rife and his technology achieve the recognition they deserved. Unfortunately, the promising period that Rife was enjoying was about to end. Beam Rays Corporation had manufactured probably fewer than fourteen units before Rife was attacked—viciously and methodically, from numerous quarters.

THE PERSECUTION OF RIFE

It was in 1939 that a series of catastrophes began, which adversely affected Rife and the many people who depended on his unit to heal them. In Chicago, Morris Fishbein was expanding his personal and professional power as head of the American Medical Association and chief public relations officer of its journal—despite the fact that he had spent only five months as an intern at Durand Hospital. “Note,” biographer Morris A. Bealle advised, “that all other medical graduates *are required* to serve two-year internships in some ‘accredited’ hospital. . . . [But Fishbein’s] accession to editorship of the *AMA Journal* was a travesty on modern medicine, since he had never practiced medicine a day in his life.”⁴²

Fishbein was notorious for writing unfavorable reviews of products whose manufacturers did not advertise in the *AMA Journal*. If advertisers paid his rates, even ineffective and unsafe products could be publicized in the journal and receive its bogus seal of approval. “Some of the products [that Fishbein slanders] are harmful,” Bealle acknowledged, “but the Fuhrer makes no distinction between worthy articles and [quack remedies].”⁴³ Among the items Fishbein condemned were ironized yeast (a nutrient, similar to brewer’s yeast), Alka-Seltzer (an innocuous and useful over-the-counter antacid containing mostly bicarbonate of soda), and Sal Hepatica (a widely publicized and effective mineral salt laxative). Anything and everything was subject to Fishbein’s public smears: he called chiropractic a “malignant tumor” and osteopathy and homeopathy, “cults.”⁴⁴

One of Fishbein's most fraudulent deceptions was the vilification of an electromedical diagnosis unit called the Ellis Microdynameter. He deliberately published a faked picture of it in the *AMA Journal*, and then submitted a falsified description of the machine to the April 2, 1935 Congressional Record. Fishbein also set up dummy corporations through which advertising revenues were eventually funneled back to him. As a result, he became quite wealthy. So did the AMA.

Many of Fishbein's investments were a matter of public record. The *Illinois Medical Journal*—which, as the publication of the Illinois Medical Society, had always been critical of unethical acts by the AMA—had proclaimed in an editorial back in December 1922: “The AMA today is a one-man organization. The entire medical profession of the United States, insofar as its organization is concerned, is at the mercy of one man and a Board of Trustees that is subservient to him.”⁴⁵

Unfortunately, the few voices raised to protest Fishbein's tactics and nearly unlimited power were unable to stop him. Fishbein was finally removed from his post at an AMA convention in 1949, but not before he inflicted a lot more damage. There is evidence that the AMA—or the AMA as represented by Fishbein—played a key role in Rife's decline by organizing agents to steal the inventor's work, undermine the Beam Rays Corporation, and halt production of the units. In “Deconstructing Beam Rays, Incorporated,” Shawn Montgomery describes this methodical scheme in intricate detail. Not surprisingly, he begins with a biography of Morris Fishbein, “the founder of America's corrupt medical status quo. . . [who] was infamous for using his sway as the powerful AMA chief to ‘buy into’ or ‘buy out’ any legitimate medical device, drug or process that crossed his path. ‘Buy into’ for profit, or, if it competes with already profitable enterprises, ‘buy out’ to suppress. This was Fishbein's *modus operandi*. It is difficult to find any information on Morris Fishbein that does not condemn him.”⁴⁶

Montgomery acknowledges that he was unable to find references that Fishbein acknowledged, quoted,

A certain amount of resistance to new ideas is normal and functional in science . . . which can result in some medical innovations being ignored or rejected without an adequate assessment. [The medical community] favor[s] the acceptance of theoretically glamorous, pharmaceutical, and high technology innovations over simpler and less profitable ones. . . . Resistance would be more understandable if the new approach were only marginally superior to the old, but that is not the case. . . . One wonders how many potentially valuable medical discoveries are being overlooked because they are too simple and not profitable enough.

or condemned Rife (or even met him). However, Montgomery does point out that Ben Cullen, a close friend of Rife's who worked in the lab, discussed at length the Fishbein “conspiracy”—a discussion that was recorded on tape. Furthermore, Cullen's account was corroborated by Rife's associate Henry Siner, by Rife himself, and later by Rife's attorney, Bertrand Comparet. Apparently, Fishbein had heard about Rife from a man with a malignant tumor who was cured by the Rife Ray. “Through this man,

Fishbein not only discovered Rife, but saw verification as to the reality and efficacy of this procedure. According to Cullen, Fishbein then dispatched two [representatives] from Los Angeles . . . to approach Beam Rays Corporation and attempt to buy into the company.” Beam Rays declined their offer, so Fishbein's representatives then “bribed one of Rife's partners, Philip Hoyland, with \$10,000 to compel him to proceed as their agent—or, as Cullen calls it, their ‘stooge.’” With the assistance of a high-priced lawyer, Hoyland “attempted a hostile takeover of Beam Rays

through a contrived lawsuit aimed at replacing the Board of Directors (and positioning Hoyland and his gang as the replacements).” This included “conspiring with C.R. Hutchinson”—a corporate entrepreneur who saw an opportunity to get rich by promoting the technology that cured cancer—“to slowly freeze Rife out of their shared ownership deal.”⁴⁷ There were additional deals and “side” deals, designed to split up the ownership of Beam Rays Corporation even more. The structure of the corporation was not only incredibly convoluted, but also probably illegal.

Another unscrupulous act Hoyland committed was the complete redesign of the Beam Ray. Montgomery points out (just as Comparet had) that the device could not be patented—for it was “a variable frequency generator hooked up to a helium tube. It couldn't do anything different enough or distinct from already existing equipment to be eligible for patent consideration. It was obvious to all that the only things of value in the process they were endorsing (or selling) were the MOR frequencies. And they only had value if they were

secret.”⁴⁸ Of course Rife, Hoyland, and a very few trusted associates knew the frequencies—but the company’s board of directors, executive officers, and shareholders did not. If the frequencies were common knowledge, there was nothing to prevent others from building their own equipment. This would mean no compensation to Rife for his vision, energy, time, and hard work. Therefore, Hoyland started building the units to disguise the frequencies as well as the methods used to generate them. See Insert, “Decoding the Mysteries of the Rife Machine.”

One might generously concede that Hoyland’s redesign of the Beam Ray was justified—except, as Montgomery summarizes:

It wasn’t long before it became apparent that Hoyland’s revamped design for the Beam Ray Machine was unstable. Hoyland was constantly called upon to go to the doctor’s office and “fix the machine”: recalibrate dial settings, service a leaky tube, solve overheating issues, solve “frequency drift” problems. As the summer of 1938 waned, Beam Rays Corporation started to become unglued. [From] reading the letters, transcripts [and] depositions, there is a sense that a stark realization was slowly dawning upon them—both collectively and as individuals—that this hastily arranged business venture might be as inherently unstable as Hoyland’s machines were turning out to be.⁴⁹

Making a bad situation even worse, Hoyland also defrauded a group of wealthy British doctors who had paid for several ray units, but to whom he sent incompletely assembled and improperly calibrated equipment—which, as a result, did not operate correctly. Attorney Bertrand Comparet later called it “deliberate sabotage. . . . They [Rife and his associates] wanted a saleable instrument and Hoyland was making junk.”⁵⁰

One of the most sad and frustrating aspects of this whole situation was that Royal Rife passively allowed it to happen. Like many geniuses devoted to science, Rife refused to get involved with the business end of his beloved research. Montgomery bluntly states:

He could do just about anything he wanted to when it came to tinkering, building, conceptualizing, formulating or configuring. But when it came to “the art of people,” Rife was a bit of a dummy. Rife was the first one to admit that he was not a businessperson. Imagine his trepidation at having among his inventory of inventions a little box that demonstrably cures cancer and any infectious disease—a thing that

not only needs to be marketed, but demands it. So what did Rife do? He started giving away ownership and control of his invention in order to pass this “business responsibility” onto others. He signed over 55% ownership of the Beam Ray device to Philip Hoyland. Rife gave him a controlling interest because he felt that would provide just enough incentive to make it work. Rife’s attorney [at the time] . . . the man responsible for notarizing the agreement, thought this was insanity and counseled Rife to substantially reduce Hoyland’s percentage. But Rife was adamant. Hoyland had designed and built the version of the machine in question while working for Rife over the last few years for very little pay, [so Rife thought] it was fair. . . . A pliable, vulnerable and somewhat inept . . . Rife allowed himself to be manipulated by people he trusted . . . [including Philip Hoyland, who used him] as a document-signing puppet.⁵¹

After the trial, Ben Cullen stated that Philip Hoyland had admitted to him that although he had accepted the ten thousand dollar bribe “to scuttle the whole Beam Rays operation,” he later “was very sorry and wished to God he’d never accepted it.”⁵² But by then, the damage to Rife was irreparable. Even though Hoyland lost the court case (and of course left the company), Beam Rays Corporation had spent so much money on the case that it was now bankrupt.

With all these crises, it’s not surprising that Rife began having a problem with alcohol. Attorney Bertrand Comparet would later confirm that Rife’s affinity for alcohol was catalyzed by his fear of being put on the witness stand during the trial. After the trial ended, however, Rife couldn’t quit. Drinking would continue to be a problem for the rest of his life.

Around this time, a law was passed by the Federal Communications Commission that heavily impacted Rife with yet another burden. (The FCC grants licenses to broadcasters who meet its requirements.) The new law prohibited the transmission of a certain range of RF frequencies without a license. The law was intended to protect radio broadcast stations and their listeners from stray RF signal interference. But it also prevented Rife’s therapy from being administered because the Rife Rays relied on radio frequencies as an integral part of the treatments. To comply with the new legal requirements, Rife had to completely reconfigure his units.

For this new task, Rife hired electronics engineer Verne Thompson. Thompson, who’d had experience as a police radio repairman for the San Diego Police Department,

Decoding the Mysteries of the Rife Machine

How Did He Do It?

Royal Rife's best machine, when calibrated properly, had an over 90% success rate in eliminating conditions ranging from *Staph* infections to cancer. But not all of his units were successful. This has led contemporary researchers to ask: What made some machines effective while others were not? Also, why has it been so difficult to consistently duplicate Royal Rife's most promising cases? These questions are important, because a significant failure rate for even one serious condition can cost people their lives. Despite an impressive track record for nearly every health challenge, many modern units have too often been unsuccessful when used to treat cancer. While they have worked far better than chemo and radiation—if only by reducing pain and improving quality of life—Rife researchers (and those who are ill) have wanted and expected more.

Equipment manufacturers, wanting to duplicate Rife's successes, have constantly experimented with different designs. We finally have a good frequency for cancer. But this wasn't always available. For those interested in history, here is an account of some of the obstacles that researchers have had to overcome in order to resurrect Royal Rife's best technology.

Unearthing the Relics

The major obstacle to learning the secret of Rife's success has been the lack of reliable data, in part due to incomplete historical records. For a long time there were tantalizing but only partial clues from what was available: Rife's surviving lab notes, decades-old correspondence, early film footage, and photographs. Then in 2001, someone discovered many reel-to-reel audiotapes in an old trunk, featuring discussions between Rife and several colleagues. The recordings were converted to CD and made available to the public. Listening to Rife and his friends discuss the equipment and case studies provided more information as to how his equipment worked, but critical information was still missing.

Around the same time, what was believed to be an original Beam Rays machine was found in an obscure location and carefully dismantled by a British research team that included engineers Aubrey Scoon and Stuart Andrews. Analysis showed that Royal Rife appeared to have borrowed a number of components from the work of other groundbreaking inventors, including Nikola Tesla, Georges Lakhovsky, perhaps Reinhold Voll, and especially Albert Abrams. The researchers also knew that Rife's equipment had

been redesigned more than three different times, at one point to accommodate a new FCC law regulating the use of radio frequency wavelengths. How a unit operated depended on when it had been built and who had built it. Unfortunately, existing photos did not provide enough details about the equipment to provide definitive clues. Plus, as it turned out, this museum Beam rays equipment was not one of Rife's best units. The team misidentified it, and mistakenly believed that it worked when it didn't. This led them to formulate plausible, but incorrect, theories about how the machine generated frequencies.

In 2004 an elderly nurse, who had been associated with Rife and worked with John Marsh (one of Rife's colleagues in his later years), gave boxes of valuable documents and audiotapes to US frequency generator builder Jeff Garff. Three years after, Garff and a small group—which included Jason Ringas of the now-defunct Rife Research Group of Canada and engineer Jim Peters (an older gentleman familiar with tube technology)—deciphered a schematic of a Beam Rays Corporation instrument built by Philip Hoyland. A working model was made, using antique parts that were still available. However, the schematic of the device was incomplete and the group could only guess how the device worked. Their guess, although reasonable, turned out to be incorrect. Thus more time was spent on a dead end.

One year later, in 2008, Garff purchased a Beam Rays instrument—one of the original ones that had been built in the 1930s by Beam Rays Corporation—from Dr. Larry Low of Toledo, Ohio. Around the same time, Garff reported that he obtained a copy of the original 1939 Beam Rays trial manuscript, which stated that the Beam Rays Corporation had produced two different designs: the laboratory model and the clinical model. From reading the trial testimony, Garff and engineer Jim Peters realized that the schematic they owned belonged to the laboratory model, while the actual instrument that Garff had obtained was a clinical model. Now they had to untangle which machine was doing what. By 2010, the original Beam Rays clinical model was repaired and various features were evaluated with a spectrum analyzer. The analysis disclosed that Philip Hoyland—who became Rife's engineer in 1935, and who in 1936 began building the clinical device that was sold by Beam Rays Corporation in 1938—had deliberately obscured how the frequencies were transmitted. This made it virtually impossible to determine what those frequencies actually were.

The Deceptions

Shawn Montgomery gives an excellent description of the various ways in which some of Royal Rife's machines were altered, configured and disguised.

As . . . different versions of the Beam Ray Machine came out of Hoyland's workshop, it started to become something that was so technically far removed from Rife's original approach that it was (from Hoyland's perspective) debatable whether or not Rife had a stake in it anymore. Rife's old device was . . . big, clunky, modular . . . Hoyland's new machines were smaller, sleeker, and portable. Hoyland combined recent advances in electronics with sophisticated circuit design, more advanced than the "old school" circuitry Rife had employed. . . . On Rife's old device the dial settings indicated the frequency of the output signal. . . . Hoyland's new machines took the MOR frequencies and hid them within the circuitry of the machines so that the dial settings would not give the true output frequency, but an encoded numeric equivalent. The output signal on Hoyland's machines was generated by an indirect means within the machine, unlike Rife's original device (whose output signal was generated directly). . . . Rife's old machines were designed to mainly present the frequency in question, and Hoyland's new machines were designed to mainly hide the frequency in question.

This brings us to the final point of difference in the two machine camps. Rife's original machines were high-frequency devices. He found that the MORs for most bugs were in the radio frequency (RF) range, very high. So Rife's frequency instruments were designed to provide maximum power at these higher ranges. Hoyland changed all of that—and in doing so, he messed with the frequencies. Hoyland's idea was to convert Rife's discovered MOR frequencies by . . . translating them down to a lower [frequency]. . . . The result was a whole new set of numbers, a whole new set of frequencies, a whole new set of MORs, a whole new electronic encryption method to scramble these new numbers, a whole new waveform, a whole new power signature (fundamentally different than the old one), a whole new bandwidth, a whole new approach—a whole new machine.⁵⁴

Had Hoyland built the Beam Rays Corporation devices in a straightforward way, their mode of operation would have been easily interpreted by modern researchers. Although Hoyland was not able to take over the Beam Rays Corporation, he did accomplish his goal of deceiving others who might try to duplicate the original technology.

Besides the problems caused by Hoyland, lab notes from various periods caused a great deal of confusion. The frequency for the same pathogen was sometimes recorded differently for different machines. Which was correct? Some of Rife's notes on the cancer virus, and on the filterable forms of *Bacillus typhosus* and *Bacillus coli*, contained errors because the generators that Rife was using had technical limitations. It would not be until 2016 that the British Rife Research Group would finally issue a paper with the correct numbers.

Another problem was, there were two RF (radio frequency) signals coming from a single ray tube. Were there two MOR frequencies for one pathogen? We do know that with tuberculosis, two MORs were needed so that both forms of the dangerous microbe were destroyed—otherwise, the infection would return if only one form was targeted. However, with two signals, it was usually difficult to tell which frequency was the actual MOR. And what purpose did the non-MOR signal serve?

What about the effects of combining two frequencies, which produced other complex frequencies called *sidebands*? Was it only one of the frequencies that existed *within* the sidebands that turned out to be the pathogen's actual MOR? How much depended on what machine was being used?

Then there was the issue of the waveform. Some researchers insisted that the shape of the wave was the deciding factor in achieving cures. Sine waves are gentler than square waves, and the harmonics they contain are negligible. What effects on the body's tissue did each waveform have, and did the different wave shapes affect the pathogens differently?

Some researchers claimed better results with only certain noble gases in the plasma tube. Others wondered whether plasma was needed at all. Couldn't metal electrodes contacting the body be used instead of a light tube, as both appeared to function equally well as transmitters? And, although some experimenters believed that an RF carrier wave was needed to drive the frequency into the body, other experimenters obtained good results without an RF carrier wave. Considering the possible biases of the researchers—some of whom built and sold their own frequency equipment—how could the average person know the truth?

What about many of the audio range (lower) frequencies that a few of Rife's associates began using in the 1950s? Many of these numbers worked, but what contributed to improved well-being? It's possible that, in addition to pathogen devitalization, the body's immune response was being boosted or regulated. Medical doctor Robert P. Stafford, a colleague of Rife's who used the technology extensively until his death, believed that some of the frequencies were effective not because they targeted noxious microbes, but because they stimulated the adrenal glands and supported immune function, thus helping the client's own system fight the infection.

Contributing Factors Challenging Us Today

Modern researchers are frustrated that some disease states are more difficult to eliminate now than in Rife's time. Several factors contribute to this difficulty:

- ◆ *Lengthier sessions.* People may have required briefer sessions in Rife's time due to differences in the design of the original equipment. However, we don't have enough data, thanks to the medical establishment's ban on Rife's machines.
- ◆ *Multiple pathogenic causes of cancer.* Besides Rife's *BX* and *BY* viruses, several other pathogens appear to play a role. These include the Human *Papilloma* Virus (implicated in cancer of the uterus, penis, ovaries, nose, esophagus and lung); Hepatitis B and C (liver cancer); and the bacterium *Helicobacter pylori* (stomach cancer). Targeting Rife's cancer virus is still mandatory for cancer, but these other pathogens need to be addressed when necessary.
- ◆ *Virulent new pathogens.* We now must deal with dangerous microorganisms that (partly due to genetic engineering) cause more damage and are much harder to treat than those confronted by Rife and his medical colleagues. To name just a few, there are Lyme and its equally hard-to-treat co-infections; Morgellons (characterized by strange fibrous, non-living parasites); and methicillin-resistant *Staphylococcus aureus* or MRSA (the result of our overuse of modern-era antibiotics).
- ◆ *Toxins.* Over the past century, the unprecedented use of harmful debilitating chemicals, food additives, and genetic engineering (not only of microbes, but crops) has made us more susceptible to new diseases and degenerative conditions.
- ◆ *Electrosmog.* Rife and his contemporaries didn't use cell phones, computers, microwave ovens, and other gadgets that cause severe DNA damage.

One issue that Rife himself did not publicly discuss was the normalization of tissue. In hindsight, it's clear that the therapy was about more than simply killing or devitalizing pathogens. Cancer cells have a much lower membrane potential (lower voltage) than normal, non-cancerous cells—as evidenced by the electromagnetic (EM) signatures that they emit. The Rife Ray's EM field contained many different wavelengths known to beneficially affect living tissue. These effects included the restoration of cellular voltage, which corresponds to increased energy, the removal of waste (including chemical carcinogens), and the more efficient intake of nutrients. All these are functions of healthy cells, not unhealthy cells. Related to this, we don't know what frequency was used to eliminate cataracts in the 1936 clinic. Was the frequency that Rife used restorative in nature? Or did it involve pathogens? If so, which one(s)?

Another topic not addressed by Rife, but considered by modern researchers, is the likelihood that the EM field from the Rife Ray was either tapping into restorative scalar waves directly, or helping the body tap into them. (See page 215 for more information on scalar waves.)

One more area of debate in the Rife research community is the effectiveness of electrode (pad) units versus ray tube (radiant plasma) units. Devotees of radiant plasma units point out that Rife was not happy with the later change of design from a ray tube to electrodes—and that if he wanted to use electrodes or a metal antenna in his initial units, he would have. He may have chosen gas-filled tubes because of the many different types of fields emitted by radiant plasma that produce a beneficial effect. However, it cannot be denied that electrode devices are very effective as long as the correct frequencies are used. Clinical trials worldwide show that both methods of delivery work. However, there are some advantages of radiant plasma units that electrode units don't have, and vice-versa. These differences relate to how each piece of equipment delivers the frequencies, how each delivery method affects the body, and the health conditions under which each type of machine should or shouldn't be utilized. (See Chapter 4 for detailed information.)

After many years of conjecture, failed experiments, and jubilant successes, we are closer to knowing what made Royal Rife's best machines so successful. However, we must not remain stuck in the past. We can acknowledge Rife's contributions while striving to improve his technology. How this therapy will evolve to meet the needs of these complex, stressful times is in the hands of future rifers.

had been doing all the repairs on Rife's equipment after Beam Rays Corporation closed. In the early 1940s, Thompson and Rife designed a new ray tube instrument that, although patterned after the best Beam Rays device, was quite different. The RF in the KHz and MHz ranges in Rife's previous instruments had interfered with radio broadcasts on at least one occasion, and could have done so in the future. So, to comply with the new law, this new device utilized low frequencies in the hertz Hz ranges. I'll discuss the details of this shortly; but for now, let's continue with the attacks on Rife.

The systematic attempts to undermine Rife continued. "The [American] Medical Association ruled," writes Vassilatos,

that no [state medical] society member who maintained use of the Rife Ray tube system would be permitted to continue medical practice in the United States. Morris Fishbein . . . extended his legal arm to inform each member of the Rife team of the impending legal process. All Ray tube units would be recalled, impounded, and destroyed by Federal Court order, under penalty of fines and imprisonment.⁵⁴

The AMA did as it had threatened. It applied its clout with the state medical societies to forcibly close any clinic that was using ray equipment. Every doctor was threatened with the loss of his license and a malpractice lawsuit unless his unit was relinquished—a difficult constraint, as these doctors had paid for their machines. Dr. Richard Hamer, who had bought a Rife Ray in the late 1930s, was one of the physicians who reluctantly visited an AMA office, probably in San Diego. Rife researcher Dave Felt relays a conversation about that era with Dr. Hamer's son Don: "Dr. Hamer was told—we don't know by whom—to get rid of the machine or lose his MD license. Don said that

his dad was really excited and happy with the machine, and that it worked extremely well. But he had to comply."⁵⁵

Dr. James B. Couche, as well as his colleague Dr. Yale, refused to relinquish his machine. "These two surgeons later stated," Vassilatos reports,

that for 22 years after this action, they continued to successfully treat and cure thousands of patients with the Rife Ray tube devices which they secretly maintained. Dr. Yale published a large and concise chronological account of patients treated and cured in his practice throughout that 22-year period. Notwithstanding the fact that 60% of severe (cancer) cases brought him were medically [inoperable], incurable, and hopeless, Dr. Yale confirmed that all of these persons were yet alive and living happy, full lives.⁵⁶

Threats and intimidation are key ploys used to coerce people into submission. However, successful suppression also means altering the historical record. This prevents people from realizing that things used to be different (better). With their memories altered or wiped clean, entire populations tend to remain more submissive and complacent. Vassilatos writes:

Fishbein, the editor and chief censor of the AMA, saw that Rife's name would be stricken from all . . . publications, that no professional journal would dare publish anything by Rife, and that no mention would ever be made of Rife's achievements in formal proceedings. Inescapably linked with the pharmaceutical trusts, Fishbein's actions were all too conspicuous.⁵⁷

Barry Lynes recounts similar orchestrated attempts to rewrite history. Twenty years after the historic 1931 dinner honoring Kendall and Rife, some of the attendees denied that the Universal Microscope worked, that they had been present at the dinner, or that they even knew Royal Rife at all. These denials are astounding, considering that many of these people had been publicly quoted in newspapers and magazines as having worked alongside Rife—and that a photograph taken of the banquet attendees had been publicly distributed! The intimidation tactics must have been severe indeed.

One can only imagine how Rife must have felt after being betrayed by some of his formerly supportive colleagues. Consider Arthur Kendall, who isolated and noted the pleomorphic characteristics of typhoid bacillus with Rife, and then published a paper on their findings. After retiring to Mexico in 1942, he wrote to the California Department of Public Health that his

Corruption Has Many Faces

Alfred Sloan and Charles Kettering, the founders of the Memorial Sloan-Kettering Cancer Center in New York City, had long and prosperous careers at General Motors, the car manufacturer. Although Kettering discovered that adding grain alcohol to gasoline would boost mileage, eliminate knocking in the engine and limit poisonous fuel emissions, he later abandoned this high-performance gasoline formula in favor of inferior-performing lead additives that every industry mogul knew were highly toxic.

contact with Rife had been very limited. Alvin Foord of the Pasadena General Hospital, who did the pathology tests for Dr. Johnson during the 1934 clinical trials, later denied any involvement at all.

With support from backers of Fishbein, a heavily organized, public slander attack on Rife and his colleagues escalated. Participants included the allopathically-oriented American Medical Association, the American Cancer Society, and Memorial Sloan-Kettering Cancer Institute in New York City. Executives from the Rockefeller Foundation, who were friends with the chief administrators of the AMA, also denounced Rife and his technology. All of the establishments that attacked Rife were partially funded by or directly connected to the pharmaceutical industry. Note that Sloan-Kettering specialized then, as now, in treating cancer with radiation and chemo. It also had, and continues to have, administrative ties to the American Cancer Society. (See Sidebar, “Corruption Has Many Faces,” for yet one more side of this institution.)

Organized meetings were held in which doctors who had never even looked at microorganisms through the Universal Microscope condemned Rife’s research, the frequency therapy, and the doctors who used the technology. Rife’s supporters were blasted by the press, professionally and personally intimidated, and threatened with the loss of their practitioner licenses. The abundant funding and resources that had been Rife’s in the 1930s were no longer available, which made the mass production of a high-powered Rife Ray no longer feasible.

It was during (and despite) this time of intense AMA intimidation and harassment that Dr. Raymond E. Seidel and M. Elizabeth Winter published their article on “The New Microscopes” in the February 1944 issue of *The Journal of the Franklin Institute*. However, the publication of this article was an exception. Despite the prestige of Rife’s defenders—and the hundreds of articles that had appeared in newspapers and journals like *Scientific American*, the July 13, 1932 “Proceedings of the Staff Meetings of the Mayo Clinic,” and publications of the Franklin Institute and the Smithsonian Institution—after the mid-1940s, most of the positive publicity for Rife evaporated. Furthermore, publications containing articles on the Universal Microscope were disappearing from archives and libraries. In 1986, Steve Ross of the World Research Foundation stated that in the US, no references could be found to Rife or his microscope in any of the 350 electronic databases that the organization was using.⁵⁸

Those who insist that they surely would have heard of Rife and his inventions had they “been any good” need only observe the methods used to suppress his work. If Rife’s supporters could be pressured enough to rescind their support, withdraw financial backing and even deny knowing him, imagine what the general public—which had no firsthand experience of the man or his inventions—could be persuaded to think. The Rife Ray clearly worked. The Universal Microscope could easily have shown how microorganisms respond to their environment. Plus, there were the proofs of people’s lab reports and clinical results. But here was simply too much money invested in allopathic drugs and its affiliated businesses—doctoring, hospital care, anesthesiology, surgical supplies—to allow a non-invasive modality to be widely utilized. If frequency therapy worked, then expensive drugs and other allopathic treatments might not only be rejected, they could even become obsolete, no longer the only or even the main healing modality. The best way to rebalance the system would be through non-invasive methods, rather than from the ingestion of poisonous drugs.

Rife’s misery deepened. And then, in October 1944, a different kind of tragedy struck. According to a coroner’s report secured by Dave Felt, Milbank Johnson died of a rupture in his heart just before his 73rd birthday. Even though the friendship between Johnson and Rife had become so strained that they had not spoken to each other in seven years, Johnson had still been a close friend, sponsor, and champion. To Rife, losing Milbank Johnson may also have felt like losing a vital connection to a better past. Rife continued to drink to relieve his stress.

To be fair, not everyone in the medical community who opposed Rife’s technology was motivated by greed. A sizeable number of doctors had trouble accepting the fact that the tiniest microorganisms, such as viruses, could be seen live through any microscope. It had never been done before. Also, “live” meant that these minuscule organisms could do some pretty amazing things—such as change their form, size, function, and virulence. If microbes could transform, and their transformation was based on the terrain in which they lived, this put the responsibility of healing back into the hands of the sick. It also meant that some cherished beliefs about biology, biochemistry, and medicine were invalid. To those whose identities were based on entrenched establishment beliefs, pleomorphism not only seemed like science fiction, but it threatened their sense of self.

A few doctors knew, or had heard of, colleagues who'd looked through the Universal Microscope and had seen what Rife saw. But they were still skeptical. Now, it's understandable if one cannot accept favorable second-hand reports from even highly respected colleagues—after all, empirical evidence is much more convincing (and more scientific). But it's harder to fathom the fear of researchers and doctors who refused to even *look* through the microscope. One would think that they'd want every tool available to help the people they said they wanted to serve.

Still other professionals looked through the microscope and did not see the specimens at all. How could this be? Lynes analogizes their intractability to the reactions of the Fuegian natives who were met by the explorer Magellan in 1520:

When Magellan's expeditions first landed at Tierra del Fuego, the Fuegians, who for centuries had been isolated with their canoe culture, were unable to *see* the ships anchored in the bay. The big ships were so far beyond their experience that, despite their bulk, the horizon continued unbroken: the ships were invisible. This was learned on later expeditions to the area when the Fuegians described how, according to one account, the shaman had first brought to the villagers' attention that the strangers had arrived *in* something which although preposterous beyond belief, could actually be *seen* if one looked carefully. We ask how could they not see the ships, . . . they were so obvious, so *real*. . . . Yet others would ask how *we* cannot see things just as obvious.⁵⁹

The reason Vassilatos gives is not psychological, but monetary. RCA was the manufacturer of an electron microscope, which competed with Rife's.

Regardless of why others failed to see what Royal Rife and his enlightened contemporaries saw, however, the outcome was the same. For Rife, to fall from a position of being respected and praised to being ridiculed and ignored—not to mention being betrayed by friends and seeing decades of work pilfered and destroyed—was more than he could bear. By 1950, he was drinking daily. He still conducted some experiments, wrote, and was contacted by professionals and a few friends. But the vital foundation of his work no longer existed.

Then in October 1957, Royal Rife's wife Mamie died. The loss of this major source of comfort and love in his life was another trauma. We can only speculate the effect that this had on the scientist.

JOHN CRANE, JOHN MARSH, AND THE NEXT GENERATION OF FREQUENCY DEVICES

Seven years prior to Mamie's death, Rife met John Crane. To pay for food, Rife was selling his remaining equipment piece by piece. Crane bought a huge amount of everything, although he did not compensate Rife nearly enough for what he bought. (When Crane's house was later raided, many items—among them photographs, medical records, reports, and pieces of the Universal Microscope including some very expensive hand-cut quartz prisms—were stolen by government authorities.)

The year 1953 brought another key player to the Rife saga: John Marsh. Marsh had recently moved to San Diego to obtain medical treatments for his wife, who had cancer; but her doctors said that there was nothing they could do for what they believed was a terminal condition. When Marsh was assigned as supervisor to John Crane at their workplace, Convair Aeronautics, Crane told Marsh about Rife. After considerable persuasion, Rife gave them an old Beam Rays instrument, which they repaired. Marsh's wife was cured after six sessions.

While the 1930s Beam Rays unit benefited the Marshes, it could not be distributed for public use because it lacked the qualifications for a new FCC license. If Rife's technology was to survive, his equipment had to contain newer electronic components that would not only make them accessible to the average person—portable, affordable, and easy to use—but also follow the FCC's legal requirements. Thus a new company, Life Labs Inc., was born. Rife, John Crane, and John Marsh worked together in the 1950s and early 60s on new instruments based on Rife's technology. Verne Thompson was hired by Life Labs to make their equipment, updating the audio frequency instrument he had built around 1942. In 1953, the AZ-58 was launched.

The AZ-58, also a ray tube instrument, transmitted frequencies in the hertz range and of course did not interfere with radio broadcasts. The wave shape was a *square wave*—literally squared-off and flat on top (as compared to a rounded sine wave), and containing (odd numbered) harmonics. These harmonics can produce effects similar to those of a higher-frequency sine wave only to a limited extent, because after about the ninth harmonic the power is so weak that the signal is no longer effective at devitalizing pathogens. Nevertheless, changing the waveform from sine to square to obtain harmonics, and also lowering the frequencies by a factor of 10, did enable the units to finally start working the way they were intended.

Garff believes that Marsh and Crane regarded the lower frequencies as Rife's intellectual property and considered

the AZ-58 to be Rife's instrument. He cites, as evidence, a plaque on the front of the device with Rife's name on it. However, during an interview in the 1970s, Comparet stated quite clearly that Rife had expressed displeasure with the AZ-58, and "indignantly denied" that Crane was "still using the Rife principal,"⁶⁰ as the unit had undergone too many radical changes.

We know that the AZ-58 did no harm. But the all-important question is, did it heal? Physician Robert P. Stafford, who spent many hours with the AZ-58 from 1957 to 1962, faithfully recorded its performance. He was pleased that the AZ-58 worked very well for most health conditions. However, it did not substantially help people with cancer. Dr. Stafford wrote, "As yet, we have failed to 'cure' any case of advanced, terminal malignancy. It appears in several instances that we may have impressed the disease favorably, [but only] temporarily."⁶¹

Meanwhile, more legal trouble was brewing. In 1958, the State of California Public Health Department compelled Crane to attend a hearing to discuss the shortcomings of the AZ-58. The unit had been independently tested by four facilities—Palo Alto Detection Lab, Kalbfeld Lab, UCLA Medical Lab, and San Diego Testing Lab—all of which verified that the equipment did not emit harmful radiation. However, this didn't prevent the state from bringing Crane and Marsh to trial in spring 1961 on charges of medical misconduct. Comparet would later comment on the tactics used to entrap the two men:

When anybody is apparently giving the medical monopoly a hard time, they go after him. . . . They [hired] some harmless looking housewives who were . . . fitted with wireless microphones, and down at the end of the block here were the [California] State men in a van with their recording equipment taking it down. . . . I remember one tape: here was Marsh in his own voice, clear as could be, saying, "This instrument will not only cure every known disease, it'll cure some we haven't yet discovered." To be fair to Marsh, John Crane was making the same type of claims, but he just didn't get caught.⁶²

Comparet also described how Crane risked breaking the law to help others. The customers of Crane and Marsh, he said, "were ignorant people. You couldn't simply hand them the instrument and tell them, 'Go home and use it.' They didn't have brains enough. So Crane went there with his instrument and operated the thing himself to make

sure it would be done correctly."⁶³ One customer was a woman whose condition markedly improved "until finally they [probably her doctors] told her she should go to the county hospital and get a blood transfusion. And she came back from that in very much worse shape, and died a week or so later. He [Crane] had to admit on the stand [that] he and Marsh had gone there and operated the instrument to give the treatment, and neither of them had an MD license. . . . That's why John Crane served his time."⁶⁴

As for Royal Rife, now almost 73 years old, he was in no state to endure the stress and indignity of another trial. He secluded himself in Mexico and refused to come to the US as a witness. No notarized medical reports in favor of the frequency instrument—either from physicians or their clients—were allowed at the trial. Rife's own written

testimony, in the form of answers to questions posed by Crane's lawyer, wasn't introduced into the record because, Comparet later explained, Rife (understandably) refused to come to court and testify.

It's worth noting that Crane had previously invited numerous governmental agencies and private organizations to test the AZ-58. Among those he contacted were the United States Department of Health, Education and Welfare; the National Research Council Committee on Growth; The American Cancer Society; The Damon Runyon Fund; Memorial Sloan-Kettering Cancer Institute in New York City; and the International Cancer Clinic. No one expressed interest in testing the device.

Rife had strong feelings about this. "The American Cancer Society," he wrote in the document submitted to (and rejected by) the court, "was interested until they found out that John Crane and I are not medical doctors . . . then they called John Crane from New York and stated that they had decided to cancel the proposed project which would have shown them how to isolate the virus, make it virulent, grow the cancer tumors and how to electronically eliminate the cancer." One can imagine his frustration as he continued:

They spend millions on drugs but nothing on electronics, unless it will supplement drugs like X-ray and radioactive treatments, which put terrible scar tissue and burns inside the body. And then the person has to have a great amount of dope and pain killers to keep the pain down. The drug racketeer makes \$10 billion annually on cancer alone [*this was in the 1950s*], and with this money they have been able to have an unconstitutional law put on the books which stated that people

More Rife History: the John Hubbard Interviews

In 1947, pathology student John Hubbard discovered the *Journal of the Smithsonian Institute* article on Rife's Universal Microscope. Excited, he sent letters to all of the optical companies, asking if they had any information on the microscope. Not one did.

Almost thirty years later, Hubbard—who was now a tenured Professor of Pathology at State University of New York at Buffalo—read Christopher Bird's article on that same Universal Microscope while browsing a magazine rack. Hubbard contacted Bird, who fortuitously had learned the whereabouts of engineer John Crane, Rife's former associate who was still living. Bird was looking for an expert in microscopy and pathology to help him assess the instruments that Crane said were in his possession. So their quests merged: Hubbard and Bird began working together to unearth and examine a Rife microscope (to satisfy Hubbard), as well as a Beam Rays machine (to satisfy Bird). From John Crane, they obtained a list of about a dozen people who were still alive and had known or worked with Rife. They traveled to San Diego, Los Angeles, Chicago, and even England. Over the course of many years, Professor Hubbard conducted most of the interviews. He also recorded them.

In 1976, Hubbard visited the San Diego court records room and obtained microfilm of most of the 1939 Beam Rays trial documents: affidavits, depositions, subpoenas, demurs, court motions. Thanks to his record-keeping and interviews on tape (along with other surviving letters and documents), the history of Royal Rife is more complete.

will only be treated for cancer by medical doctors with X-ray, radioactive treatments, and surgery—creating a drug monopoly.⁶⁵

Except for the few labs that had tested the device solely to make sure it did no harm, no medical society, hospital, clinic or organization ever tested the units on human beings to see if it could heal. The only medical opinion represented at the trial was from a doctor who had been given a unit to test two months previously and decided that it didn't work—even though he openly admitted *in court* that he had never tested or evaluated it! The jury was comprised of people with no medical background, except for the foreman, who was an allopathic doctor opposed to the entire concept of frequency therapy.

The AMA board under the Director of Public Health declared the frequency instrument unsafe, and banned it from the market. Both Marsh and Crane served three years of jail time and were released in 1964, with orders not to associate with one another.

Still, the AZ-58 refused to die. Just before Crane's incarceration, he and Marsh reconstructed the device so it transmitted frequencies via electrodes rather than the more expensive gas-filled glass tube. A common, off-the-shelf audio frequency generator costing around \$200—standard equipment in many labs—was used to produce the frequencies, because it's easier and cheaper to buy a mass-produced item than to build something from individual parts. This new device had no RF carrier. It utilized square waves and frequencies in the hertz range.

John Marsh continued to build pad and ray tube instruments until his death in 1987. His activities

were not as widely publicized as Crane's. Crane sold electrode units after his release from prison. Noted for his tendencies for hyperbole (as well as for being an opportunist), he claimed benefits from this new device that seemed even to surpass results achieved by Rife's original ray. This new machine was touted as successfully treating chronic bladder irritation, cataracts, fungal growths on the hands, growths over the eyes, anal fissures, pyorrhea, arthritis, ulcerated colon, varicose veins, prostate troubles, colitis, back pain, and heart attacks. Crane also wrote a lengthy, creative manual on how to use Rife Therapy with pad devices and the additional elements of polarity, color, and magnetism.

This new pad device birthed a new generation of rifers. However, Crane's units were expensive. An engineer who bought a unit from Crane shortly before Crane died, told me that it was an ordinary audio frequency generator with nothing remarkable about it. Crane had modified it with a new front panel, a power booster, and a few dollars worth of hand-held metal cylinders to use as electrodes. This unit, nicknamed the "Rife-Crane device" or simply the "Crane device," sold for five times its original cost.

Politely put, this was not Rife's technology at its finest, either in design or intent. However, the "Crane devices" provided a valuable function. They helped keep the technology alive. If there was a chance that this technology was valid, then successful versions of it might be reconstructed sometime in the future.

Royal Rife died in 1971. John Marsh died in 1987, and John Crane died in 1995. Fortunately, Rife's technology did not die with them. A new phase of this research was about to begin.

THE CONTINUAL SAGA OF PLEOMORPHISM

Virginia Livingston-Wheeler

In 1947 (one year after Rife's laboratory closed), on the East Coast of the United States, physician Virginia Livingston-Wheeler discovered a bacterium she named *Progenitor cryptocides*, Greek for "hidden killer." This normally harmless pathogen, she stated, was present in humans and animals, but causes cancer when the immune response is not working properly. She also pointed out that immunity is compromised by exposure to chemical toxins, emotional stress, and poor diet.

"A specific class of microorganism apparently belonging to the mycobacterium has been observed and is grown from the cancerous blood and tissues of [human beings] and animals," she wrote. "They [the pathogens] are *filterable and pleomorphic*." The various diseases associated with this family of pathogens included "scleroderma, interstitial myocarditis, . . . fibrosis, pleurisy, pericarditis, rheumatic fever, nephritis, hepatitis and arthritis, *depending on the degree of host resistance, the invasiveness of the specific microorganisms, the strain specificity, and the site of tissue susceptibility*." [emphasis added]⁶⁶

Livingston-Wheeler's findings, notes dermatologist and cancer researcher Alan Cantwell, "angered cancer experts, microbiologists and American Cancer Society spokespersons, all of whom continued to insist the cancer microbe did not exist."⁶⁷ The resistance was active: after the innovative doctor presented her discoveries to the 6th International Congress of Microbiology in Rome in 1953, the New York Academy of Medicine immediately issued a statement discounting her findings. Dr. Cornelius P. Rhoads, head of Memorial Sloan-Kettering Cancer Center, stopped all funding for the Rutgers-Presbyterian Hospital Laboratory where Dr. Livingston-Wheeler worked.

In contrast, the European medical community showed a high level of tolerance and even appreciation. In July 1958, when Livingston-Wheeler spoke at the 1st International Congress of Microbiology and Leukemia in Antwerp, Belgium, she discovered that for many years, European doctors had understood, accepted, and worked with the reality of pleomorphism.

In 1959, Livingston-Wheeler—having moved to San Diego, California, four years before—met her neighbor, Royal Raymond Rife. Livingston-Wheeler arranged for the Institute of Cancer Research in Philadelphia to provide Rife with mice, and for about a year the two worked together. Although they held similar views on pleomorphism, Livingston-Wheeler focused on developing a serum to cure cancer instead of working with Rife's technology. In her San Diego, California clinic, people

were treated with diet, nutritional supplements, and a vaccine prepared from their own diseased tissue. Her treatments were successful overall, but the medical authorities closed her clinic.

Dr. Livingston-Wheeler died in 1990. But before her death, she expanded her research with three other remarkable women. See below.

Eleanor Alexander-Jackson

In her Cornell University lab in Ithaca, New York, microbiologist Eleanor Alexander-Jackson witnessed pleomorphism in the tuberculosis bacillus as she watched it change shape and size. In 1948, Dr. Alexander-Jackson had a meeting with Dr. Livingston-Wheeler. Together, they found a special acid-fast stain that highlighted the microbe so it could be recognized both in a Petri dish culture and inside a cancer tumor.

At the time, the way to differentiate a virus from a bacillus (bacterium) was to pass it through a special filter. Tiny viruses could pass through the filter, whereas the larger bacteria could not. The two researchers found that

Pleomorphism has been taught to medical students for a long time. *Taber's Cyclopedic Medical Dictionary* (first copyright 1940), defines pleomorphism as "1. Property of crystallizing into two or more different forms. 2. Occurrence of more than one form in a life cycle."⁶⁸ A major textbook used by medical students, *Harrison's Principles of Internal Medicine*, states that "*Acinetobacter calcoaceticus* . . . was described by DeBord as *Mima polymorpha* in 1939. It is one of two well-characterized varieties of *Acinetobacter*. . . . Organisms described as *Bacterium anitratum* and B5W are synonymous with *Acinetobacter*. These organisms are pleomorphic, gram-negative, encapsulated, and non-motile. They grow well on ordinary media, forming white, convex, smooth colonies. Diplococcal forms predominate in colonies grown on solid media; rods and filamentous forms are more common in liquid media."⁶⁹

Despite the above, there's a difference between distinguishing a diplococcal form from a rod form of the same microorganism, and the idea that a microorganism can morph into something that is so fundamentally different in size, form, function, and damage potential, that it becomes a completely different organism. Few medical personnel want to believe that a pathogen might exist in the body as a harmless structure until the host's terrain changes it.

An Internet search reveals at least eight heavily documented textbooks on pleomorphism published in German, complete with references and photos.

the acid-fast organisms found in scleroderma, leprosy, tuberculosis, and cancer could change from small forms that could be filtered into large forms that could not! This meant that the viruses morphed into bacteria and the bacteria morphed into viruses. What science had carefully catalogued as separate and discrete pathogens were *the same microbe changing form*. It is these changes in shape and form (and thus function) that cause the different symptoms we call disease.

In 1966, Drs. Livingston-Wheeler and Alexander-Jackson presented a paper at an American Cancer Society seminar in Arizona. When Alexander-Jackson returned to her laboratory at Columbia University in New York City after the seminar, she found that she had been fired from her research position.

Irene Corey Diller

Cellular biologist Irene Corey Diller was an exemplary employee at Philadelphia's Institute for Cancer Research. Famous for discovering and isolating fungus-like microbes in cancer cells, she published "Studies of Fungoid Form Found in Malignancy" in 1953.

Now the research team numbered three. Once she was joined by Livingston-Wheeler and Alexander-Jackson, Diller worked with mice specially bred for a tendency to develop cancer. After injecting healthy mice with cancerous microbes cultured from tumors taken primarily from human breasts, she more than doubled the rate of cancer in the mice. From these mouse cancer tumors, she successfully cultured the same microbe—thus proving that these pathogens were involved in the development of cancer. These experiments were similar to those conducted by Royal Rife. Utilizing Livingston's methods, Diller also grew the microbe from the blood of human beings with cancer.

Florence Seibert

Born in October 1897, chemist Florence Seibert was considered one of the foremost authorities on the chemistry and immunology of the acid-fast bacteria that cause tuberculosis. In the 1920s, Dr. Seibert had devised a method to make intravenous transfusions safe by eliminating contaminating bacteria. She was heavily decorated. In 1938, the National Tuberculosis Association awarded her the Trudeau Medal—the highest prize given for tuberculosis research—for perfecting the skin test for tuberculosis (used worldwide). In 1942, Seibert received the Garvan Medal from the American Chemical

Society. Later in 1990, she was inducted into the National Women's Hall of Fame.

By 1959, Seibert had retired. However, she was so impressed with Diller's research that she began working again in the early 1960s to help prove that bacteria cause cancer. Dr. Alan Cantwell, who befriended all four women and considers them mentors for his own research, reports:

Experiments conducted by Seibert and her research team were able to isolate bacteria from every piece of tumor and every acute leukemic blood they studied, proving these acid-fast and TB-like cancer microbes were not laboratory contaminants.

In her autobiography, *Pebbles on the Hill of a Scientist*, published privately in 1968, she wrote: "One of the most interesting properties of these bacteria is their great pleomorphism. For example, they readily change their shape from round cocci, to elongated rods, and even to thread-like filaments, depending upon what medium they grow on and how long they grow. This may be one of the reasons why they have been overlooked or considered to be heterogeneous [various, dissimilar] contaminants. . . . Even more interesting . . . these bacteria have a filterable form in their life cycle . . . they can become so small that they pass through bacterial filters which hold back bacteria."⁷⁰

Seibert's research, like the experiments of others before her, clearly pointed to the ambiguous boundaries between presumed discrete pathogens. "Seibert's provocative papers, some emanating from the prestigious Annals of the New York Academy of Sciences, should have caused a stir," Cantwell comments.

But with these four women slowly closing in on the infectious cause of cancer, funds from previous supporters (such as the American Cancer Society) suddenly dried up. . . . After [Dr. Seibert's] death, . . . the obituaries mentioned her contributions to the safety of intravenous fluids and her great achievement with the TB skin test, but not a word was written about her cancer microbe research, to which she devoted the last 30 years of her life.⁷¹

When Dr. Seibert died in 1991, she was bewildered by the medical industry's lack of interest in finding the cure for cancer. "It is very difficult to understand," she

wrote, “the lack of interest, instead of great enthusiasm, that should follow such results.”⁷² Difficult, indeed! One author reports that in 1985, the Sloan-Kettering Cancer Institute found “the Rife-Livingston-etc. organism (virus) in all blood cultures of cancer patients. They conclude[d] that the organism [came] from outside contamination and bur[ie]d the report.”⁷³

Lida Mattman

In 1997, American biology professor and microbiologist Lida Mattman was nominated for a Nobel Prize for her work on stealth pathogens. With 35 years of experience working in the fields of immunology, microbiology, bacteriology, virology, and pathology at numerous schools and institutions, Mattman was well qualified. Her specialty was *Borrelia burgdorferi*, a pathogen that causes Lyme disease—and a pathogen that she proved is pleomorphic. In her definitive textbook, *Cell Wall Deficient Forms: Stealth Pathogens*, Mattman described how *Borrelia burgdorferi* can survive and spread without having a cell wall. In its cell-wall-deficient state, Lyme is very dangerous because it can’t be detected by the body, by almost all pharmaceutical antibiotics, and even by a fair number of natural herbs and essential oils. Nevertheless, Dr. Mattman was able to culture the Lyme bacterium from its cell-wall-deficient form and grow it into spirochetes in a laboratory.

The Lyme spirochete’s ability to morph into other forms is not quite like the other examples of pleomorphism because the bacterium is still recognized as *Borrelia* no matter what form it assumes. Nevertheless, Dr. Mattman’s discoveries have helped countless people who suffer from Lyme because now they know how to approach eradicating the pathogen. Her findings may also help doctors recognize the incredible variability of microorganisms in general.

Ludwik Gross

Ludwik Gross was an oncologist and virologist who repeatedly stated that many different types of cancers were caused by viruses. His book, *Oncogenic Viruses*, was published in 1970. In 1974, he noted won an Albert and Mary Lasker Foundation prize for his discovery that leukemia can be transmitted by a virus.

Despite Dr. Gross’s generally favorable reputation, circumstances obliged him to write, in a 1978 issue of the journal *Cancer Research*, that “there was considerable reluctance and often even frank hostility on the part of leading investigators to accept, as facts, these new and fundamental observations.”⁷⁴ As Gross later explained, “Research projects and experimental approaches radically

different from such accepted concepts or theories were not only frowned upon, but often resulted in the refusal of the necessary financial and logistical support needed by the investigator to carry out his proposed studies.”⁷⁵ His obituary in *The New York Times* (he died in July 1999) stated that “for the half-century before Dr. Gross’s discovery, scientists had largely ignored the role of viruses in cancer even though, beginning in 1908, researchers had suggested a viral cause by transmitting leukemia and sarcomas in chickens.”⁷⁶

Clearly, scientists all over the globe have known for over a century that pleomorphism plays a role in cancer and other illnesses. If you change the terrain, you change the illness, even controlling whether it occurs at all. This is a simple concept. Yet for some, it’s difficult to accept—so difficult, that they don’t want others to know about it.

Gaston Naessens

Born in France in 1924, microbiologist Gaston Naessens later moved to Quebec, Canada, where he designed an unusual and powerful microscope called a Somatoscope. The instrument uses polarized light from an ultraviolet source and magnifies live specimens up to 30,000 diameters their size instead of the usual 2,500 diameters. As did his predecessors, Naessens saw tiny entities in the blood, which he called *somatids*. By now, you can guess the rest of the story. Naessens reported seeing 16 somatid cycles, the first three of which are normal. If the system becomes unbalanced, the somatids evolve into any of 13 other stages of bacterial, viral, or fungal forms. Naessens linked these pathogenic somatid forms to a host of degenerative diseases, including cancer, rheumatoid arthritis, AIDS, lupus, and Multiple Sclerosis. He has a history of successfully predicting which disease condition will develop according to the microorganisms that are most prevalent in the blood.

To combat cancer, Naessens formulated a compound called “trimethylbicyclonitramineoheptane chloride,” which was shortened to simply “714X.” Still used today, it contains camphor (derived from the shrub *Cinnamomum camphora*), ammonium chloride, ammonium nitrate, sodium chloride, ethanol, and water. Every day, the 714X is injected into a lymph node in the groin. One round of treatment consists of 21 daily injections. Three series are the minimum amount required, and most people need to receive longer-term treatment. The 714X injections mobilize the immune cells and unclog the lymph system, so it’s the body that kills the cancerous tissue.

Naessens’s effective injections are available in Canada, Mexico, and Western Europe. However, in the United States, the FDA has banned all sales of 714X.

Kurt Olbrich and Bernhard Muschlien

In 1972, German engineer Kurt Olbrich left a career as one of the top research analysts in the plastics industry and formed the Institute for Interdisciplinary Basic Research. At the institute, Mr. Olbrich provided analysis services for various industries and research organizations—using, among other tools, a microscope. But the scientist's research was hindered. It was the same old story: existing light microscopes could not provide the resolution, depth of field, and image quality he needed for his work. So in 1976, after extensive research, Olbrich discovered a new way of building microscopes. By using a unique mathematical approach to optics, he avoided the constraints of existing optical theory and built a microscope with a resolution better than 100 nanometers, and with unparalleled depth of field, full contour sharpness, and true vivid colors.

Like Rife's Universal Microscope, Olbrich's invention allowed long-term viewing of microorganisms in their living natural state. There was never a need to kill the specimen, stain it, or use oil immersion. Olbrich's equipment, which worked on different principles than Rife's microscope, had an even greater resolution. It was also very easy to operate. Later, Olbrich created a more affordable series of microscopes with the same features. He named the initial microscope, as well as its successors, the *Ergonom*. In 2002, the first instrument designed for sale was marketed by Grayfield Optical Inc., a company with bases in the United States and Europe.

Today, at the Institute for Interdisciplinary Basic Research, Kurt Olbrich continues to do research and analysis—this time, with the benefits of his own instrument. The *Ergonom* has been used to conduct a detailed analysis of Legionnaires' disease, leading to several published articles. German natural health practitioner Bernhard Muschlien, in conjunction with Olbrich, has utilized the *Ergonom* microscope to provide foundational material for his published articles on pleomorphism and also for his film, "Symbiosis or Parasitism." (For company contact information, including access to the articles and film, see Appendix A.)

As might be expected, it was inevitable that the *Ergonom* would be used for cancer research. Olbrich has extensive experience observing the blood of people with various stages of cancer as well as those whose

blood indicates a precancerous condition. Some of the images and material in the widely read German medical textbook, *Pleomorphismus* (published by Haug Verlag), are based on Olbrich's observations through the *Ergonom*. In his series of drawings, Olbrich has standardized the measurements (in nanometers) of morphing biological life forms that live in the blood. The scientist describes the oncogenous blood parasite as a *cancer virus*—a term he chose because it appears to be a virus-like organism, even though most of the forms he has observed are fungal. While Olbrich's observations might appear radical to an uninformed American audience, the majority of Germans—both practitioners and laypersons—have known about pleomorphism for a long time and welcome his research. Olbrich's drawings, in the Insert called "The Olbrich Sanguinogramm: Development Stages of *Mucor racemosus*," are on pages 236–239.

Peter Walker, a Europe-based Rife researcher and personal friend of Olbrich, points out some little-known facts about the way viruses appear under an electron microscope. His account provides an excellent reason, when assessing the blood, to use a microscope that does not kill its specimens.

Under an electron microscope, viruses not only die, they also shrivel up like a fist—so what you see is not what viruses normally look like. For example, textbooks teach that the HIV virus is about 30 to 40 nanometers, because that is the size as seen under the electron microscope. But in reality, such viruses can grow to nearly 300 nanometers when seen in their living state—a fact established during a trial in Berlin using the *Ergonom* microscopes.⁷⁷

Royal Rife's last known existing, working microscope is being kept in a safe, undisclosed location, hidden away from people who might want to steal it. This is good for the microscope, but not so good for scientists who would benefit from using it. However, thanks to Mr. Olbrich's perseverance and inventiveness, professionals can now conduct serious research in an unlimited number of fields: medicine, biology, biochemistry, geology, electronics, archeology, electromedicine. The possibilities are unlimited. We finally have the optics needed to not only corroborate the research of Royal Rife and his successors, but to finish what Rife began—and even surpass him.

IMPLICATIONS FOR HEALING

Now that we have the microscope technology to confirm the findings of Royal Rife and others, groundbreaking experiments can be taken to a new level. Dr. Alan Cantwell—who studied with Dr. Mattman as well as doctors Livingston-Wheeler, Alexander-Jackson and Diller, and did not even have access to the Ergonom when he did his experiments—flatly states:

From my work at the VA [hospital] with Eugenia [Craggs, a microbiologist specializing in tuberculosis], I learned one important thing: microbes change form. Sometimes they appear one way, sometimes another. And they could fool the experts. The appearance of the microbe depended on what it was fed in the laboratory. In the textbooks of microbiology the classification of organisms was simple and straightforward. But in reality, it was not that way at all.⁷⁸

When dealing with a live person or animal, the appearance of a microbe depends on the terrain that is the inside of the body. And that terrain depends on what the host has eaten. Changing the terrain not only can change the characteristics of a harmful microorganism, but in most cases determines whether that pathogen will even exist.

I began this chapter by describing two opposing concepts of illness and disease that did or did not subscribe to the germ theory. You have seen how unscientific ideas become embedded in public consciousness to such a degree that they eventually are cited as “proof,” despite their lack of scientific validity and their defiance of common sense. As long as the medical-pharmaceutical industry continues to insist on—and impose—its own version of what illness, wellness and medicine are all about, the advancement of holistic protocols will be ridiculed, suspended, and even forbidden. A true revolution in health care can only occur when enough people are willing to “think outside the box.” This means that instead of taking the latest toxic drug, and more toxic drugs, people will embrace the need to change what they eat and drink as well as how they conduct their lives. They will take responsibility to heal themselves, instead of giving away discernment and self-reliance to an outside authority.

Since the first edition of this book was published, I have received thousands of phone calls, letters, and emails from people all over the world. In most cases, they were not only willing, but eager to take responsibility for their own healing. Quite a number of correspondents were doctors

and scientists, ready to act as healing facilitators and investigators rather than as unquestioned and inflexible authority figures.

The new paradigm of medicine can no longer be concealed or suppressed. People are waking up and are hungry to learn the truth. Not only is the lay public becoming more discriminating in their choices of healing modalities, but they are also actively seeking out many types of electromedical modalities, including the technology that Rife created.

Hundreds of different frequency devices are being used worldwide for therapy. Not only are companies producing electromedical devices, but individual experimenters are building their own. Although Royal Raymond Rife was the only person who ever constructed a real “rife machine,” this doesn’t mean that modern units don’t work. They do. However, with the rapid increase of infectious and degenerative diseases, we need them to work even better, and faster.

In Europe and other parts of the world, which have a relatively enlightened understanding of medicine and more legal tolerance, frequency therapy is being used openly by many doctors and clinics. In North America, although laypersons and even doctors are (often secretly) using frequency devices, the manufacturers and sellers of the equipment are not allowed to make medical claims for them. Likewise, most media—at least American mainstream newspapers, magazines and television—is silent about this technology. This makes it difficult for the average person to obtain information on Rife Therapy, unless the seeker is very determined or has Internet access.

Happily, this situation is changing. The general public is more aware of Royal Rife now than they were even five years ago. Also, more people than ever are becoming interested in alternative healing methods—alternative, that is, to the allopathic medicines that have been pushed onto us like any other consumer item. The more we take responsibility to educate ourselves, the less satisfied we are likely to be with the status quo. This is as it should be.

Now that you know how promising Rife’s sessions were, you probably can’t wait to begin rifeing yourself. Chapter 5 organizes diseases and degenerative conditions, along with their frequencies, in a user-friendly manner. But before we get there, it’s important to know what to do when all those pathogens start to die in your system. Chapter 3 discusses many complementary and detoxification modalities, all compatible with Rife Therapy. Whether used with a frequency unit or without one, these protocols will help your overall healing be faster, easier, and more effective.

The Olbrich Sanguinogramm: Development Stages of *Mucor racemosus*

Kurt Olbrich has extensive experience investigating and cataloguing pleomorphic forms found in the blood of people who are precancerous and who have full-blown cancer. The above drawing measures morphological phenomena in nanometer (nm) units. Olbrich calls the microbe a "cancer virus," though most forms are fungal.

Inner circle: Isolated cancer viruses.

Outer circle: Reaction of phagocytes. **A.** Normal conditions. **B.** Enlargement of phagocytes. **C.** First, attempts by the phagocytes to remove the cancer virus. After increasing in size, the viruses are released into the plasma and can then attack further cells (blood/tissue).

Construction of the Sanguinogramm is possible only by recording images of living phenomena in blood in real time. This is done through the Olbrich's Grayfield contrast microscope, the Ergonom 400. The Ergonom 400 uses normal white light, magnifying at least 25000:1 with corresponding true resolution capacity. Other equipment used includes a high-resolution video camera of broadcast quality (resolution of at least 600 lines), and a monitor with a horizontal screen size of at least 40 cm (pixel resolution better than 0.3mm). Use of such equipment allows for measurable freeze-frame images from moving objects to be created in true color without any significant electronic falsification.

Cancer Pathogens that can be seen and measured: Olbrich's original illustrations.

Potential cancer viruses as found in all blood. Their heads measure from 40–70 nm, and they have a simple flagellum.

The average head measurement is now about 240 nm. The complete length, including the doubled flagella, is about 1000 nm. This form corresponds to a weakened immune function, as when one is battling a severe case of influenza. After the person recovers, the original pleomorphic state automatically reestablishes itself, and viruses with twin flagella die.

This phase (called the "B" phase by Kurt Olbrich) begins when one's immunity is weakened over a longer period of time. The head now has an approximate diameter of 450 nm. The total length, without the head, is about 1500 nm. A club shaped formation is created. In the head, new infectious particles can already be detected.

Here, a total length of about 6000 nm has been attained, the head measuring about 1000 to 1500 nm. The development of new viruses can be clearly seen. The end is jagged, probably to more easily attach to nerve surfaces and thus absorb more nutrition than what is available in the blood serum.

The formations are developing further. Once a total length of about 10 μm has been reached, the circular head formation explodes and young viruses emerge. The head diameter is about 24 to 35 nm and the structure possesses a simple flagellum. Now the cycle is complete.

Erythrocytes are attacked and become nutrient food for the pathogens.

Here the erythrocytes (red blood cells) are depicted as spheres, with an exterior measurement of about 6000 nm. The cancer viruses, with a head measurement of up to 50 nm, penetrate the surface of the erythrocyte membrane and emerge again with a head measurement of up to 70 nm.

The larger spheres are blood cells containing cancer viruses, whose head measurements are over 90 nm. A flagellum is present, although it cannot be determined if the tail is single or double at this stage.

Here, the viruses try to pass from the inside to the surface of the membrane. At this stage, the head size is about 150 nm, the tube-like exit has a diameter of about 200 nm and a length of about 500 nm.

The development continues. It is unclear whether or not the viruses have developed into spores. The diameter of each virus head is about 240 nm, and the length of the tube-like exit is about 1250 nm.

Cancer Parasites grow into fungal mycelia.

Here, the diameter of the erythrocyte is only about 5000 nm, whereas the tube-like tendrils emerging from the sphere are still about 1000 to 1250 nm. Pronounced ball-shaped formations are now developing at the ends.

The fungi threads separate from the erythrocytes. The ball-shaped formations have a diameter of about 540 nm.

From the shell of structure number 5 (see first, circular diagram of this series), fungal threads are now formed. This is most likely the stage where the metastases enter the blood.

Until a man duplicates a blade of grass, nature can laugh at his so-called scientific knowledge. Remedies from chemicals will never stand in favorable comparison with the products of nature, the living cell of a plant, the final result of the rays of the sun, the mother of all life.

Healthy Living and Complementary Therapies

INTRODUCTION

You're sick. And you're sick and tired of being sick. Maybe you've been chronically ill, with debilitating symptoms. Perhaps your symptoms are merely inconvenient, causing minor discomfort. Or, your condition may be life-threatening. Regardless of your situation, though, you want to get better, now!

Desperate, you borrow or buy a frequency device and begin rife sessions, determined to kill or disable the pathogens that are making you sick. But halfway through the first session (or maybe just after it), instead of feeling better, you feel worse. You're achy and nauseated, dizzy and disoriented. Or you develop a headache and sore throat, as though you're catching the flu. Perhaps you have muscle and joint pain, bloating and cramps, skin eruptions. Or you feel fatigued, unable to concentrate. You notice that your urine has turned a bright yellow (unconnected to the golden color it sometimes turns when you take more vitamin supplements than you need). Regardless of your response, you wonder: *Why do I feel so rotten?*

These responses are normal. The technology is simply doing the job for which it was created: the destruction of dangerous microbes.

Pathogens lead busy lives. They steal your nutrients, appropriate your cells, and excrete waste into your bloodstream. They also reproduce, ensuring that more of their nasty little selves will soon emerge to commit the same abuse. After the pathogens are rendered less active

(or in some cases made to shatter) by rifting, garbage is everywhere. The corpses of these harmful critters, along with the toxins they spew, are clogging your bloodstream. The debris floods your tissues and joints, impeding lymph drainage. Junk you never knew existed seeps through the blood-brain barrier, impairing your ability to think, feel, and move. Your immune cells engulf the waste as fast as they can (although it doesn't feel fast enough to you). Once the immune cells have consumed their fill of rubbish and are no longer functional, they'll have to be eliminated.

You'll need all the help you can get to excrete the toxic mess resulting from the rifting. And make no mistake about it: Once you find frequencies that match what ails you, there will be plenty to clean up.

Often, the only help you will need to relieve (or eliminate altogether) the symptoms from pathogenic die-off is to drink more water. More water in the body decreases the ratio of microbial toxins to bodily fluids. If you don't drink, you'll become poisoned from the waste. If you're unwilling to drink more water, I urge you not to rife at all, because otherwise you can make your condition worse. The kind of water to drink, and how much, will be discussed in the next section.

But what if you don't feel any of the above-mentioned symptoms? Does that mean the sessions aren't working? Not necessarily. If there are enough minerals in your system, you won't experience many (or any) symptoms. The detox (also called *Herxheimer*) response is discussed in detail in Chapter 4.

Even if you don't experience die-off symptoms from rifting, you will benefit by using one or more of the complementary modality discussed in this chapter. Some of these modalities (dietary protocols, herbs, sunlight, exercise, bodywork), focus primarily on strengthening the body and building tissue. Other modalities (color therapy, electrolytically isolated/colloidal silver, ozone), both restore cells and tissues and eliminate pathogens. Still other protocols (sauna therapy, poultices, homeopathy somewhat, and again the multifaceted ozone), focus more on detoxification, although there's an overlap with other functions.

Detoxification is also known as "cleansing" for good reason. It eliminates debris, related to illness or stress, that—if not eliminated—can toxify or poison the body. Excessive debris encourages the proliferation of pathogens and leads to cellular degradation, and ultimately degenerative conditions. Don't underestimate the importance of detoxification; it plays a vital role in remaining healthy. It's like clearing old dead leaves from a stream to allow the water to flow freely again.

I have always preferred to rely on myself as much as possible for my own health care. Plus, I like to use therapies that are reasonably priced. Therefore, I almost exclusively present inexpensive, effective protocols that can be self-administered. Also, the information and protocols in this chapter are generally under-represented in, or sometimes entirely absent from, not only mainstream but also holistic circles. These carefully selected overviews are designed to inspire you to continue researching on your own.

What if you don't have access to a rife machine? Or you're not sure that rifting is for you? You will still want to read this chapter. Incorporating one or more of these modalities into your wellness routine could be just what you need. I urge you to consider the dietary suggestions, along with at least some of the other protocols in these pages. You may be surprised to discover that most of the therapies are easier to implement than you think—and that they address your situation in ways you might never have considered.

If you have a stubborn or serious medical problem, it's always wise to consult someone knowledgeable. However, as most allopathically trained medical doctors lack the training, open-mindedness, or inclination and time to investigate, administer or counsel about these therapies, I suggest that you see someone skilled in holistic approaches.

WATER

Water's Unique Properties

Water is much more than something we gulp to wet our throats. Like the oxygen we breathe, it's essential to life. The body contains an amazingly high amount of water. According to the *Nutrition Almanac*, in a normally hydrated adult the blood contains 83%, the kidneys 82%, muscles 75%, the brain 74%, the liver 69%, and bones a surprisingly high 22%. All of our vital functions require water. Susan Kleiner, author of "Water: An Essential But Overlooked Nutrient," explains:

Fluids fill virtually every space in cells and between them. Water molecules not only fill space, but they also help form the structures of macromolecules such as proteins and glycogen. As the primary fluid in the body, water serves as a solvent for

minerals, vitamins, amino acids, glucose, and many other nutrients. Water also plays a key role in the digestion, absorption, transportation, and use of nutrients. Water is the medium for the safe elimination of toxins and waste products and whole-body thermoregulation is critically dependent on it. From energy production to joint lubrication to

reproduction, there is no system in the body that does not depend on water.¹

My own path towards wellness has been a long and dynamic one. It's taught me that healing from the inside out takes time, and there can be great value in various sources of guidance.

—Carre Otis, American model and actress, (born September 28, 1968)

No wonder people can survive for about a month without food, but would die in several days in even a mild climate without water!

Water has another unique property. It's an ideal *universal solvent*, due to its ability to dissolve *solutes*, or whatever is dissolved in it, without undergoing a chemical change itself. In its entirety, a water molecule has a neutral charge. However, the tetrahedron-shaped molecule is positively charged on one end and negatively charged on the other. This enables water to pull apart other molecules and reduce (dissolve) them into their basic elemental forms. For instance, with table salt (sodium chloride), the water that surrounds it acts like billions of tiny magnets to pull apart the compound mineral and reduce it to its original sodium (Na⁺) and chloride (Cl⁻) forms.

A water molecule consists of the elements hydrogen (H) and oxygen (O). Separately, they exist as gases. Together, they create a liquid when two atoms of hydrogen are combined with one atom of oxygen (H₂O).

Water Sources and Treatments

The source of the water that we drink does not always indicate its purity or quality. Our drinking water supply is usually from among the following:

- ◆ *Tap Water / Municipal Water Supply.* Municipal water usually comes from a reservoir (artificial lake specifically created to supply water to towns and cities). Reservoirs are fed by rain, and occasionally by ground or spring water. The town or city supplying the water filters the water (which is beneficial), but then adds dangerous chemicals to it. The amounts and kinds of chemicals are determined by the local government.
- ◆ *Spring / Well.* This comes directly from the ground near your house, through pipes, and into your faucet. If the well supplies a certain number of dwellings, by law the water must be periodically tested, and in some cases treated for contamination.
- ◆ *Carbonated.* The water can come from any source. It may or may not already contain naturally-occurring carbonation. The water is filtered or distilled, infused with carbon dioxide—even if it's already naturally carbonated—and then bottled.
- ◆ *Filtered.* The filtration is usually done on-site where the water will be used (private home or office). It can be done with activated charcoal, reverse osmosis, ultraviolet, ozone, a combination of these, or another system supplied by the consumer. The source of the water can be a municipal water supply, spring, or well.
- ◆ *Distilled.* The water (which can be from any source) is boiled, evaporated into steam in a chamber, and then condensed and collected in another chamber. Distilled water can either be made with a home distiller, or commercially bought in plastic containers. The source of the water can be a municipal water supply, spring, or well.

The Importance of Decontamination

An alarmingly high amount of our drinking water is contaminated with industrial waste, sewage, pesticides, detergents, and even drugs (as discussed in Chapter 1). Lawsuits against industry are becoming increasingly common, as more and more manufacturing plants pollute lakes and rivers with toxic chemicals. Runoff from pesticides, herbicides, and manure used on factory farms seeps into the groundwater. Some areas still don't have adequate treatment facilities, and the sewage gets into our groundwater as well.

For these reasons, virtually every holistic practitioner and even some allopathic doctors discourage drinking water directly from the tap. Even if the original source is pure, after the water reaches the municipal water supply it's treated with dangerous chemical disinfectants such as chlorine (used to eliminate pathogens) and fluoride. These practices are ill-advised, because for relatively little cost, safe ozone could be used instead. Many countries around the world use ozone to purify not only drinking water, but also swimming pools and hot tubs (discussed later in this chapter in the section, **Oxygen Therapies**).

Tap water is also problematic because it can pick up rust and other dangerous metals (oxidized or not) from the pipes that carry it. In some areas of the United States, I have actually seen foam spewing from the faucet. (I recall that the water in Philadelphia, Pennsylvania was particularly shocking, like a bubble bath.) Was this due to detergent-like chemicals added to "improve" the water, or to other contaminants? Sometimes it's hard to tell. Most municipal tap water in this country is noxious, and the awful taste proves it. Many people who aren't picky about what they eat still filter their water because it tastes so bad.

What type of decontamination process is best? Generally, any water (from whatever source) that's filtered to eliminate toxic metals, chemicals, particulate matter and harmful microorganisms, is safe to drink. This eliminates most municipal tap water as a good choice. What about carbonated beverages (soda water and seltzer)? Those tiny little bubbles are created when carbon dioxide (CO₂) is forced into water at a high pressure. And in nature, sparkling water is sometimes created when decaying vegetation releases its CO₂ into groundwater. But sparkling drinks, although made with filtered water, are not always a wise choice. Whether the carbonation is manufactured, is from a naturally bubbling spring, or (as in some bottled water products) is a combination of the two, when CO₂ combines with water it makes it acidic. Carbon dioxide is needed in the lungs to regulate the amount of oxygen absorbed by the body (too much oxygen in the system can be as dangerous as too little)—but when it's in the stomach, the gas can impede digestion.

Our choices, then, are mainly pure spring, filtered, and distilled water. It makes sense that any water—unless regularly tested for contaminants and deemed safe—should be adequately filtered, whether it comes from a municipal water supply, well, or spring. Who would argue against eliminating contaminants? But are there any advantages to imbibing clean spring water? And what about distilled? Let us continue.

Living Water: Water's Fourth Phase

We have always learned that water has three states: liquid, solid (ice), and vapor (in various stages of evaporation such as fog or steam). However, scientist Gerald Pollack recently discovered that water has a fourth phase, what he calls *exclusion zone*, or *EZ* water. The anomalies that water displays under ordinary circumstances—for instance, there's no single temperature at which it freezes or boils, and it clusters together in particular ways depending on what it touches—led Pollack to his experiments and proofs.

EZ water is best described as a *liquid crystal*. This liquid-crystalline water has a unique ability: it stores energy, a virtually unlimited supply of electrons, in a manner very similar to that of a battery. All EZ water possesses a negative charge. The source of EZ water's energy is the sun, whose various electromagnetic wavelengths—visible light, ultraviolet and especially infrared (most powerful at about 270 nanometers)—imparts that energy, even in darkness. EZ water builds on any hydrophilic (water-loving) surface, including in a living body. The flow of EZ water is driven by protons. (This has enormous implications for understanding the pumping activity of the cardiovascular system.)

EZ water is *living*, alkaline water. It's not H_2O , which Pollack calls *bulk* water—but H_3O , which is structured and organized. Not coincidentally, the many healing waters of the Earth contain living water. They include India's river Ganges, the Lourdes in France, and Hunza glacial waters in Pakistan. We create living water in our bodies when we use far infrared saunas, LEDs and lasers, and lie in the sun. We also create living water in our bodies when we expose "regular" bulk water to these radiant energies, transform it into EZ water, and drink it.

This implications of this liquid-crystalline fourth phase water are truly profound.

The Relationship of Minerals to Water

To answer the questions asked on the previous page, I must redirect the discussion to the chemistry of minerals. All water (except for artificially created distilled water) contains minerals. So, the function and properties of water are intertwined with its mineral content. Please bear with me if I appear to digress too far from the topic; you will see how everything fits together by the end of this section.

Minerals rarely exist as single elements. They are usually *compounds*, combined with another element or elements—sometimes other solids, sometimes oxygen, sometimes water, and sometimes a combination of these.

Even if a mineral is referred to by its common (elemental) name that suggests the presence of only one element, there is always something to which it is bound. Calcium might be calcium chloride; magnesium, magnesium oxide; potassium, potassium iodide; and so on. Sodium is commonly bound to chloride. Chlorine is a gas, but it becomes the solid chloride when it's combined with sodium, forming common table salt.

Many people assume that no matter where a mineral comes from, it will nourish them. But that isn't true. Minerals are not always in a form that humans can assimilate. And if we cannot assimilate them, those minerals can become contaminants.

Heavy Metals

There are two kinds of minerals that humans cannot utilize. The first are commonly called *heavy metals* or *toxic metals*. Heavy metals are not nutrients. Poisonous to the body, they should never be ingested regardless of their form. For the purposes of this discussion, aluminum, cadmium, lead and mercury are commonly regarded as heavy metals.

Much of our drinking water contains heavy metals. These heavy metals accumulate in the system, clogging whatever tissues they settle in: joints, blood vessels, organs, glands, bone. Once the heavy metals are trapped in the tissues, they interfere with the body's ability to function, causing serious damage. Some of the damage occurs in the form of degenerative conditions such as heart disease, arthritis, respiratory conditions, and dementia.

Two of the most common heavy metals are aluminum and mercury. Although aluminum is the world's most abundant metal, it is not needed by the human body to function. Aluminum easily combines with other substances to form compounds, many of which are widely used in industry and food manufacturing. Aluminum hydroxide is found in most antacids, sodium aluminum phosphate is put into processed cheese, aluminum chlorhydrate is used in antiperspirants, aluminum sulfate is used by water treatment plants, and so on. Although some scientists claim that aluminum must be consumed in large amounts to be poisonous, most holistic practitioners recognize the dangers of much smaller amounts. Numerous studies show that aluminum compounds produce (among other disabilities) memory loss, decreased muscle coordination, and slowed growth. Not surprisingly, the brains of people with Alzheimer's disease contain larger than usual amounts of aluminum. Mercury is equally dangerous. Even recently, mercury was used in thermometers. And it's still present in many vaccines (not that vaccines are themselves safe), and in thousands of other items, from carpeting to

compact fluorescent light bulbs. Many manufacturing plants spew mercury into our air and water, causing dangerous levels to accumulate in much of the world's fish. Because mercury lodges in fat cells, some fish that ordinarily would be excellent sources of essential fatty acids are no longer edible.

Regardless of which heavy metal is ingested, they all interfere with our vital life processes. To compound the problem, *Candida albicans* and some other pathogens feed on metals. This is why infections from dangerous microbes often exists alongside heavy metal contamination.

Unabsorbed Minerals

There is a second category of minerals that humans cannot utilize: unabsorbed minerals that are not heavy metals. Although these minerals are not poisonous per se, they are contaminants because they cannot be assimilated by the body. Thus, their effects are similar to (though not always as severe as) the effects of toxic metals.

In their most elementary state, these minerals are found in rock. Water, wind, sun, and soil bacteria break apart rock into soil. From this soil, plants extract the minerals and transmute them into a form that they can use. The humans and animals who eat the plants liberate, through the process of digestion, the minerals into a form that *they* can use. In this context, *organic* sources of minerals are assimilable, and come from plants or animals; whereas *inorganic* sources of minerals are not assimilable, and come from rock or soil.

(The terms “organic” and “inorganic” can be confusing. People interested in a clean diet know foods as “organic” if they are grown without pesticides, herbicides or synthetic chemicals. Conventionally trained chemists call compounds “organic” or “organically-derived” if they contain at least one carbon or one hydrogen atom, and term compounds that lack carbon as “inorganic.” In this current discussion, “organic” and “inorganic” are used to mean the *source of minerals*, which determines their absorbability by the body.)

Humans are designed primarily to assimilate organic sources of minerals, which is why we eat plants and not rocks or dirt. Occasionally, children do eat dirt and even small pebbles, but this isn't common. The children may instinctively be trying to obtain needed minerals in the diet. “Although the chemical analysis [of organic and inorganic minerals] is the same whether found in air, earth, plant or animal,” write father-daughter health food manufacturers Paul and Patricia Bragg in *Water, The Shocking Truth*, “it is only through the *life processes* of the plant whereby the constituents of air and soil become *vitalized* and useful to the human body.” [emphasis added]²

Most chemists study the physical nature of elements and how they interact when they're combined, but without

considering the vital life force of the element. *Electrical charge is a component of life force*. For years, unscrupulous nutritional supplement companies have taken advantage of people's ignorance by cramming their products with cheap, useless, inorganic minerals. (See the sections on **Food** and **Selected Nutritional Supplements** later in this chapter for more details on this vital force.)

To utilize precious minerals, we must ingest them in the proper form—from plants, which transform the minerals for us. There is, however, one exception: when minerals are completely dissolved in water.

Electrolytes: Minerals with a Charge

Water dissolves inorganic minerals when it flows through forests and churns around rocks, ending as a spring, creek, river or waterfall. This moving water is such a powerful solvent that the minerals dissociate from one another and become *charged particles* called *ions*. An ion can be a single atom, or a group of atoms.

Once minerals become ions, their behavior radically changes. Their electrical charge allows them to permeate a cell membrane. Normally, in an atom, the number of (positively-charged) protons in the nucleus equals the number of (negatively-charged) electrons orbiting around it. The first orbital shell closest to the nucleus holds the maximum number of two electrons, the next orbital shell holds a larger maximum number, and so on. In many atoms, the orbiting electrons do not fill their outer shells to capacity. This allows the outer-shell electrons to get bumped or rearranged fairly easily. An almost completely filled outer shell will more easily *receive* electrons, and will thus carry a *negative* charge, because there are now more electrons than there are protons. A sparsely filled outer shell will more easily *lose* its electrons, and will thus carry a *positive* charge, because there are now fewer electrons than there are protons.

It is this dance of oppositely charged particles that give us compounds in so many different and wondrous configurations, which activate almost unlimited life processes. One common example is the positively charged sodium ion (Na⁺) that combines with the negatively charged chlorine ion (Cl⁻) to create the compound mineral, or mineral salt, called sodium chloride. (See Sidebar on page 254, “The Electromagnetic Dance of Atoms.”)

(Incidentally, chemists often compare an atom to a miniature model of the solar system, with the atom's nucleus at the center like our sun, and electrons orbiting the nucleus like planets. Although quantum physicists have recently pointed out that this model of the atom is technically inaccurate, it's still the most familiar, and workable, conceptual design that we have to describe chemical processes. Hence, I am using it.)

The Electromagnetic Dance of Atoms

Elements are partly attracted to each other because of the direction in which their electrons are spinning. The electrons in the outer shell of one element will jump to the outer shell of another element only if the electrons of the two different elements have opposite spins: clockwise and counterclockwise.

Why? Because the movement of electrons (electricity) creates a magnetic field (just as a moving magnetic field can create electricity). If electrons from two different elements have *same-direction* (parallel) spins, they magnetically *repel* each other. If electrons from two different elements have *opposite-direction* spins, they magnetically *attract* each other. This magnetic attraction due to the opposite spins is so strong, it counteracts the repulsion that one might normally expect to occur between two electrons, both of which by definition possess negative charge.

This partly helps explain what takes place, and why, when people are healed with devices that influence the body's electromagnetic, magnetic, electrical, and other subtle energy fields. Just as minerals can affect the electrical and magnetic fields in the body, electromedical devices (with electrical and magnetic properties) affect the body's minerals.

It's not necessary to learn every detail about how ions are formed. The pertinent is that *the movement of energy, called electron transfer, on the electromagnetic level corresponds to a chemical reaction on the grosser material plane*. Life processes occur when the transfer of electrons take place; and minerals play a vital role in this process. "These ions-in-solution," soil scientist David Yarrow writes, "are valuable for their effects on water's [intrinsic] electrical properties. Most often, they increase water's ability to pass an electric current, or store electrical charge."³ This is why ions are called *electrolytes*.

In the body, different electrolytes are located inside and outside of the cell membrane. These electrolytes have different *electrical potential* or driving force, just like a battery. Through many complex steps involving the flow of electrons across a cell membrane, electrolytes help maintain biochemical and physiological changes crucial for life. Electrolytes are responsible for energy production; ease of respiration; maintaining the distribution of water in the body; the proper function of nerves, muscles and organs; the delivery of nutrients to the cell; the removal of wastes; and *osmotic integrity*, or uniform pressure on the inside and the outside of the cell. (*Osmosis* is the diffusion of water or particles across a semi-permeable membrane. The flow occurs from a higher to a lower concentration, until

both sides equalize with the same amount.) If our cells do not receive adequate electrolytes, among other effects the cell membrane collapses and leaks fluid. The water then becomes trapped between the cells, resulting in what we know as water retention, while meanwhile the cell itself is starved for water and all the nutrients the water carries. An unnaturally permeable cell membrane also leaves the cell more vulnerable to invasion by pathogens and the body's waste materials, which in turn acidifies the system further.

Electrolytes also play a key role in the pH (acid-alkaline) balance of the cells. Most minerals are alkalizing while a few are acidifying. We need *all* minerals to function properly, although most of the minerals required for health (calcium, magnesium, potassium and sodium) are alkaline. Alkaline minerals appear in our drinking water more often than acidic minerals, but not always.

Nothing in the body can function properly without electrolytes. All living organisms transmit an electrical charge. The stronger the electrical potential, the more vital the organism is. Low electrical potential equals illness. No electrical potential equals death. (See Sidebar, "The Amazing Story of Alexis Carrel and His Chicken Heart.")

Water and minerals have a unique relationship. The minerals dissolved in water influence its properties. Water with lots of electrolytes has a lower surface tension, which allows it to be better absorbed. Think of a drop of water on a wooden surface. If the surface is heavily waxed, the water is intact and remains where it is—comparable to the action of non-mineralized water. If the surface of the wood is not waxed, the water seeps more easily into the wood—comparable to the action of water rich in electrolytes.

It's no accident that historically, so-called miracle or healing waters have all been alkaline due to (among other factors) a high alkaline mineral content. In Europe, mineral water is defined as having more than 250 ppm of minerals. (*PPM*, or *parts per million*, is the number of micrograms per milliliter.) Not coincidentally, water that contains electrolytes tastes subtly sweet. Good water is actually quite delicious, and very satisfying as a beverage.

Just a little over 100 years ago, before the Earth became polluted with so many chemicals and wastes, there was ample living water that contained electrolytes—dissolved minerals—which made the water *conductive*, or able to carry an electrical charge. Earth's waters generally had an alkaline pH and plenty of oxygen. Today, this is the exception rather than the norm.

Purifying our water is a necessity. However, what we take out of water is as important as what we leave in. If we remove enough of the beneficial dissolved minerals, we may make ourselves ill. This will become even clearer as I discuss various purification methods.

Basic Filtering (Filtration)

Many people filter their water even if the source is an underground spring or well. Underground water can be contaminated with pathogens, or have an unpleasant taste from chemical additives or mineral deposits whose particles are too large, or are the wrong type of minerals. A good filter removes pathogens, chlorine, and large particles. It always consists of a fibrous core through which the water travels before being released for drinking. Different materials for filter cores include activated charcoal and shredded coconut shell. These substances cannot remove fluoride, although ozone can. (The dangers of fluoride will be discussed later.) In addition to fibrous cylinders, the more sophisticated water purification systems use ozone or ultraviolet light, which produces ozone. In any unit, the filter must be replaced regularly or else the core becomes overloaded with contaminants. Make sure to follow the manufacturer's advice on when to change the filters.

Home filtering units can sit on the countertop, be installed beneath the sink, or be fitted at the water's entryway into the house. Filters are important not only for drinking water, but also for bath and shower water. If your water has been pre-treated with chlorine, try to install a filter at the entryway of your home instead of on individual faucets, as chlorine is very toxic. See Sidebar on page 256, "Chlorine: A Lethal Choice for Water Purification."

One popular and inexpensive water filter consists of a small activated charcoal cylinder inside a pitcher. Water poured into the pitcher passes through the charcoal: the purification process. But most people don't bother to pour a little water over the core first and let that water go down the drain. Instead, they use *all* the water that flows through the cylinder. This means that bacteria collected in the charcoal passes directly into the pitcher, as well as the filtered water. Unless you regularly keep the charcoal core free of pathogens, I would not recommend this type of passive filter. Get a water purification unit that *automatically* puts the filter core through a cleansing cycle with fresh water. The best units also circulate ozone to kill any bacteria that may multiply in the filter.

Distillation

Distillation has become a popular method of cleaning water because it removes more contaminants than does simple filtering: heavy metals, all particulate matter, and most pathogens. (It cannot remove fluoride or volatile organic compounds.) All minerals are also removed during distillation, which is why the process is sometimes called *demineralization*. The elimination of minerals eradicates water's ability to conduct an electrical charge. This makes distilled water an excellent foundation for cleaners, cosmetics, and thousands of other preparations where an electrical reaction would be undesirable. (Distilled water

The Amazing Story of Alexis Carrel and His Chicken Heart

In 1912, French-born surgeon Alexis Carrel won the Nobel Prize in Medicine for devising unique ways to suture blood vessels, repair damaged arteries, and transplant organs. By 1935, together with famous aviator Charles Lindbergh (who was also an environmentalist and an inventor in his own right), Carrel created the first artificial heart.

But the accomplishments of Carrel's that are the most commercially publicized may not be the most important. From 1912 to 1940, the scientist kept a piece of embryonic chicken heart alive in a solution whose minerals were present in the same proportion as the minerals in chicken blood—and which had the same alkalinity (a pH of 7.35 to 7.45). Carrel was careful to change the solution and oxygen every single day. The experiment ended only because he deliberately stopped bathing the heart tissue 28 years later.

Normally, the life span of a chicken is no more than eleven years (assuming she didn't die at around age four from the stresses of commercial, continued egg laying). Carrel was able to keep the heart tissue healthy and alive because *the mineral solution nourished the cells, and the replacement of the fluids every day ensured that all the cellular waste materials were removed*. One of the secrets, then, to health and longevity is not only proper nutrition, but also *waste removal*. Carrel's mineral bath regularly eliminated the waste products of cellular metabolism!

Theoretically, there is no limit to the number of divisions that a healthy cell can undergo, provided it's kept free of metabolic wastes. This has enormous implications for theories about aging. What if so-called "aging" is largely the breakdown of the tissues due to toxification?

Interestingly, Carrel spent many years working at the Rockefeller Institute for Medical Research in New York City until the administration forced him to retire. The Rockefeller family has major ties to the medical-pharmaceutical industry. The Institute bestowed much public praise on Carrel for his undeniably spectacular surgical innovations, but was remarkably quiet about the doctor's discovery that simply keeping the body in its pristine state—with nothing more than oxygen and a mineral bath—may be one of the best-kept secrets to healing, health, and longevity.

is also needed to make colloidal silver, discussed later in this chapter.) The uniformity of distilled water, precisely due to its lack of minerals, ensures that the properties of preparations made with it are consistent with each batch. Thus distilled water is a standard ingredient for industry.

Industry requirements are quite different from drinking needs. Of all the methods to make water drinkable, distillation is the most controversial. The allegations for and against distilled water are many and confusing. It's the best water to drink; it's the worst. It doesn't leach minerals from the body; it does. Or, it leaches minerals from the body, but only the harmful heavy metals. Some people swear that distilled water healed them and they won't drink anything else. Others claim that distilled water causes severe mineral depletion, some practitioners even reporting that clients who exclusively drank distilled water upset their body's mineral balance in just three weeks. Counter arguments assert that although this depletion may occur, it can take a long time. No wonder the average person is baffled!

Water's innate ability to act as a solvent means that it will always contain some minerals. In Nature, though, water without minerals doesn't exist. Therefore, when water is demineralized, it becomes a ferocious solvent. Deprived of minerals (along with any serviceable conductivity), the

now denatured (de-Natured) water seizes minerals from anything it touches so it can replenish itself. It doesn't matter what distilled water seizes: it will grab minerals, metals, chemicals, acids, anything that can dissolve in it.

The thorough removal of minerals via distillation gives water a totally neutral pH of 7.0, at least theoretically. In reality, the pH measurement is lower. Because distilled water is so reactive, the instant it's exposed to air it reacts with carbon dioxide, a naturally acidic gas. This creates carbonic acid, which becomes part of the overall solution. The presence of carbonic acid instantly makes the water acidic. My freshly made distilled water has never tested above 6.8; usually it measures 6.4 or 6.5. My tests of commercially distilled water (bought in supermarkets) have shown even more acidity, with a pH sometimes as low as 5.8. You can test the pH of your own water with a colored fluid available at pet stores, which is used for aquariums. This works better for water than pH strips, which are more accurate for bodily fluids. People struggling with high levels of acidic wastes may be palpably harmed by drinking acidic water.

The carbonic acid issue aside, what are the effects of drinking water that doesn't contain any minerals, or is low in minerals? In "Water—The Choice for Long-Term Health," Michael Donaldson explains:

Chlorine: A Lethal Choice for Water Purification

Chlorine, commonly added to municipal water supplies to kill pathogens, is very dangerous and highly reactive. It readily combines with other substances to form a variety of toxic compounds, including carcinogenic trihalomethanes, nitrogen trichloride (a cause of asthma in chlorinated pools), and other byproducts. These chemicals cause, among other problems, birth defects; cancers of the bladder, bowel, breasts and kidneys; fertility problems; heart disease, including high blood pressure and hardening of the arteries; and immune breakdown.

Chlorine was originally used as a rarefied, deadly weapon during World War I. However, it is so widespread now that its use seems normal. Aside from poisoning the body outright, chlorine—like its chemical relatives fluoride and bromine—displaces the beneficial mineral iodine. This leads to an incredible variety of health problems. Without iodine, the thyroid gland cannot manufacture thyroxine, the hormone used to regulate metabolism. The lack of thyroxine causes problems ranging from abnormal body temperature to depression to a sluggish immune response. Without the germicidal properties of iodine, the body cannot protect itself adequately against infections, including cancer. Most of the iodine the body uses is located in the thyroid, breasts, lungs, and sinuses.

There are many ways in which chlorine can get into the bloodstream. When put into bath and shower water, swimming pools, and hot tubs, chlorine is absorbed directly through the skin. Hot or even warm bathwater causes the pores of the skin to become more open, so any chlorine that's in the water is more readily absorbed. This is why showering in chlorinated water is the equivalent to drinking eight glasses of it at once. Breathing in steam from the hot water allows chlorine to directly enter the lungs, where it damages the lungs' delicate membrane lining and contributes to asthma, bronchitis, and other respiratory conditions. Chlorine is also a serious eyes irritant, causing itching and burning. Even if no serious disease develops, the chemical dries out the skin's natural moisture barrier.

Chronic exposure to chlorine—which is not difficult, considering it's put into drinking water, bathwater and swimming pools—creates chronic inflammation. Over time, cells and tissues become damaged faster than the body can repair them; and cell damage equals disease and aging. Symptoms from chlorine exposure occur long before the chemical can be smelled, at levels over 3.5 parts per million (ppm).

There's absolutely no reason to use chlorine as a water purifier, especially when other, excellent options are available—such as ozone, and bars made from silver and copper.

In the desalination industry [which removes salt, along with all other minerals, from seawater to make it drinkable,] it is an industry-wide rule that water must be partially remineralized before sent down the distribution pipeline because . . . [it] is too aggressive and will cause severe corrosion of the pipeline. . . . One report from a desalination plant in Cyprus producing over 10 million gallons of purified water per day found that iron [from the pipes] was being leached into the water supply. By alkalizing the water [which required the addition of certain minerals]. . . the iron corrosion was stabilized.⁴

Distilled water can corrode metal pipe, but how does it react in a living body? Does it draw toxic metals to itself? What about beneficial minerals? Common sense indicates that once inside the body, any liquid becomes part of the systemic fluids, which by definition contain minerals. Therefore, distilled water will no longer be distilled. Nevertheless, there's ample evidence that distilled water can damage our health. Why is this?

The following data was not easy for me to find because many of the papers on this topic are published in languages other than English, and few have been translated. However, what I did unearth is compelling. The best research on inadequately mineralized water—which of course also applies to distilled—was done decades ago by individuals who weren't selling water filters or distillers. First I'll address water that's merely low in minerals, rather than totally lacking in them.

In 1977, a comprehensive, US government-sponsored, 939-page report called *Drinking Water and Health*, was published by the Safe Drinking Water Committee of the National Research Council. "Several hypotheses are reported on how water factor(s) may affect health," they wrote. "These mostly involve either a protective action attributed to some elements found in hard [mineral-rich] water or harmful effects attributed to certain metals often found in soft [mineral-deficient] water."⁵

Heart conditions and other health problems were strongly influenced by the quality of water.

More than 50 studies in nine countries have been carried out on the possible relationship of water hardness and health . . . A voluminous body of literature suggests that in the United States and other developed nations . . . [there is] an *inverse* correlation between the incidence of cardiovascular disease . . . (heart disease, hypertension, and stroke) . . . and the amount of hardness. . . . Studies in the United States

and Canada have shown that age-adjusted cardiovascular mortality rates among populations using very soft water may be as much as 15% to 20% higher than among populations using hard water. The differential reported for the United Kingdom may be as high as 40%. . . . A few reports also indicate a similar inverse correlation between the hardness of water and . . . risk from several non-cardiovascular causes of death [including the formation of kidney stones and the development of cancer].⁶

The authors considered all possibilities regarding where people might obtain their minerals. The form of the minerals was important, too. The minerals in the hard water that the researchers studied were completely dissolved ions, or electrolytes. The authors also noted which minerals were helpful and which were harmful.

The amount of these elements provided through drinking water relative to other sources is less important than their chemical form. It is theorized that trace elements . . . in foods . . . may be less available metabolically than the ionized form that generally occurs in water. . . . Another possible variable is the different effect of hard and soft waters on the mineral composition of foods during cooking . . . Soft [mineral-deficient] water may remove a significantly higher proportion of various "protective" nutrients and elements from foods during cooking than do hard waters. [This is because both no-mineral and low-mineral waters draw other minerals to themselves in an effort to restore balance.] . . .

Investigators have attributed the disease-protective effect of hard water to the presence of calcium and magnesium . . . [and] vanadium, lithium, chromium, and manganese. . . . The suspect harmful agents include the metals cadmium, lead, [inorganic unbound] copper, and [inorganic unbound] zinc, all of which tend to be found in higher concentrations in soft water as a result of the relative corrosiveness of soft water [which was so corrosive that it leached metals from the pipes.]⁷

The results of yet more studies, conducted outside the United States, are summarized by Donaldson.

[A Russian study] compared the populations in two cities that were supplied with different water—one with low TDS [total dissolved solids], low calcium, and low magnesium, and

the second one with higher TDS, calcium, and magnesium in the water. Other mineral levels in the water were also determined. The population in the area supplied with the lower mineral water showed higher incidence rates of goiter, hypertension, ischemic heart disease, gastric and duodenal ulcers, chronic gastritis, cholecystitis (inflammation of the gall bladder) and nephritis (inflammation of the kidneys). Children in this area with the low mineral water had slower physical development and more growth abnormalities, newborn mortality rates were higher, and pregnant women had more edema and anemia. Clearly, the minerals in the water were benefiting this population.

In another Russian study women living in four Siberian cities, which had increasing amounts of calcium and magnesium in their water, were followed for health outcomes. In the two cities with the lowest levels of water minerals there were more cardiovascular problems, higher blood pressure, headaches, dizziness, and osteoporosis compared to the two cities with the highest levels of water minerals. . . .

A study with over 4,000 women in France found that consumption of calcium in their drinking water was associated with an increase in bone density.⁸

A more recent report, *Nutrients in Drinking Water*—published in 2005 by the World Health Organization (WHO)—was written by a panel of water specialists who were examining the impact of making sea water drinkable through the process of desalination. In many parts of the world, where water is not potable (drinkable), using seawater would be a reasonable option were it not for its excessively high levels of salt, which can rather quickly cause dehydration and death. (This is due to the overload of salt on the kidneys, which cannot make urine if the salt concentration is too high.) The panel wondered about the health hazards and benefits of purifying seawater through sand, through harmful chemicals (such as chlorine), through caustic but provisionally safe chemicals (such as chlorine dioxide, also called MMS), or with ozone. Correcting the water's pH was also addressed.

The panel remarked that historically, research has focused more on the toxic contaminants and total dissolved solids in drinking water than the protective effects of its minerals. However, the benefits of minerals became highlighted due to the main concern, which was the effects of desalination. While desalination is a good method for

removing large amounts of undesirable salt from seawater, it also removes nutrient minerals. Therefore, among other questions, the panel asked: Should minerals be added after the desalination process? If so, which ones? What amounts are appropriate for infants, young children, and adults? And does diet make a difference in which minerals to add?

The panel's conclusions matched those of their Safe Drinking Water Committee predecessors. "Drinking water should contain minimum levels of certain essential minerals," including calcium, copper, iron, magnesium, manganese, selenium and zinc. "Demineralised water that has not been remineralized, or low-mineral content water . . . is not considered ideal drinking water."⁹ The numerous health effects cited were similar to those found by researchers three decades earlier.

The WHO panel was careful to explore the possibility of bias. Because much of their data was based on older studies, the members considered the possibility that some of the studies "may not meet current methodological criteria." However, they decided,

These findings and conclusions should not be dismissed. Some of these studies were unique, and . . . are not so questionable as to necessarily invalidate their results. The older animal and clinical studies on health risks from drinking demineralised or low-mineral water yielded consistent results . . . and recent research has tended to be supportive.¹⁰

Significantly, some of the research that formed the panel's above conclusion was on *distilled water*. I'll get to that in a moment. First, the panel's recommendations:

International and national authorities responsible for drinking water quality should consider guidelines for desalination water treatment, specifying the minimum content of the relevant elements such as calcium and magnesium. . . . Authorities should ensure that the guidelines also apply to uses of certain home treatment devices and bottled waters.¹¹

We are fortunate to have a report that's specifically about distilled water and its effects on health. It was commissioned not by a distiller manufacturer, but by the WHO in the late 1970s. Professor Sidorenko and Dr. Rakhmanin led a team of researchers from the A.N. Sysin Institute of General and Public Hygiene and the USSR Academy of Medical Sciences. Their conclusion? "Not only does completely demineralised water (distillate) have unsatisfactory organoleptic properties [an unpleasant taste and smell], *but it also has a definite adverse influence*

on the animal and human organism.” [emphasis added]¹²
Donaldson gives an excellent summary of the study:

Rakhmanin carried out a one-year experiment with rats using low mineral water. Negative effects were found. These rats had an increase of extracellular body water, increased sodium concentration in the blood, increased urine output, and increased losses of sodium and chloride ions in the urine. There were also hormonal changes including reduced secretions of tri-iodothyronine [a form of thyroid hormone used by the tissues] and aldosterone [an adrenal cortex hormone that regulates kidney function and balances the body's electrolytes], and increased secretion of cortisol [a stress hormone secreted by the adrenal cortex], and morphological [structure and function] changes in the kidneys. There was evidence of reduce[d] skeletal ossification of rat fetuses of the dams given *distilled water* during the one-year study . . . Many of these same findings were repeated in human volunteer studies—increased urine production (almost 20%), increased body water volume, increased sodium concentration in the blood, decreased potassium concentration in the blood, and increased elimination of sodium, potassium, chloride, magnesium, and calcium ions from the body. [emphasis added]¹³

Any discussion of water should include the variable of diet because we obtain minerals from foods. Were the people in these reports receiving enough minerals from the foods they were eating? If their diets were adequate, would they have had the same health problems from drinking water that contained few or no minerals?

Some people in the health field believe that most of our minerals, and indeed all other nutrients, should come from food. The aforementioned Braggs, persuasive advocates of distillation, correctly pointed out that distillation produces pure water in this polluted age (although they did not address its inability to filter out fluoride and VOCs). In fact, Paul Bragg was in glorious health until the day he died, well into his 90s (not from illness, but from a surfing accident). He wrote that he enjoyed great health because he drank distilled water every day, along with quarts of fresh vegetable and fruit juices and a vegan diet of mostly raw fruits and vegetables. But to ascribe the health of the Braggs to distilled water is misleading. Daily fresh juices are rich in dissolved, *ionic* minerals—electrolytes. The unusually high levels of absorbable minerals should easily offset any mineral-depleting properties of distilled water. If someone feels better distilling their drinking water, could it be that

The ORP of Water

ORP, or *oxidation redux potential* (also known as *redox*), is one of the ways in which the quality of water is assessed. When applied to water, ORP is a measurement of water's tendency to acquire or lose electrons—in other words, the degree to which it can oxidize or reduce another substance. This activity (electrical potential) is measured in millivolts.

The electron level and activity is one way to measure beneficial changes in the water. More electrons are associated with increased energy. A greater number of electrons also indicates more antioxidant properties, higher oxygenation, and an enhanced ability of the water molecules to form into microclusters. This clustering, also known as *structuring* which yields *structured water*, makes the water “wetter.” The fluid more easily crosses cell membranes, which creates more hydration.

Water's ORP level is also important because the higher the ORP, the less chance of survival for pathogens such as *E. coli*, *Listeria*, and *Salmonella*.

the previous water source was so heavily contaminated that distilled is better only by comparison?

The WHO panel did factor in the effects of diet.

It influences the evaluation of the nutrient mineral content in drinking water considerably. . . . Use of foods that are naturally rich in trace elements like zinc and iron (e.g. meat) or minerals like calcium (e.g. dairy products) is recommended, but may not be practised because these foods are not available, affordable or acceptable for the family. This may lead to reliance on predominantly plant-based or vegetarian diets of poor nutritional quality. In these situations, and depending on its composition, drinking water may contribute a considerable part of the dietary mineral intake.¹⁴

Animals greatly benefit from mineralized water too. Donaldson writes that animals who had zinc or magnesium added to their drinking water:

had much higher levels of zinc and magnesium in their blood than a comparison group that was fed much higher levels of these minerals in their food but provided with low-mineral water to drink.¹⁵ . . . [Furthermore] the bioavailability of minerals from water has been studied in people as well [as animals]. . . . Water is a good carrier of minerals. . . . Minerals in water are as available to be utilized by the body as minerals in food, sometimes even more available.¹⁶

It's worth exploring in depth how low-mineral water affects the digestive tract. As the WHO panel explained, distilled water produces "direct [undesirable] effects on the intestinal mucous membrane, metabolism and mineral homeostasis or other body functions." This causes "little or no intake of calcium and magnesium, . . . [a] low intake of other essential elements and microelements, [and] . . . loss of calcium, magnesium *and other essential elements in prepared food.*" [emphasis added]¹⁷

A complete lack of minerals—and even an inadequate intake of minerals—causes an imbalance of those minerals that are already in the body. Once the imbalance starts, the body tends to retain more sodium than necessary and excretes other vital minerals such as potassium, magnesium and calcium. Loss of these vital minerals leads to increased stress (due to augmented levels of stress hormones); abnormally soft bones (at least in developing rat fetuses, and we must assume in humans as well); and excessive bloating (due to the tendency of water to seep between the cells where it doesn't belong, instead of inside the cells where it does belong). Thus, many outright nutritional deficiencies can be *caused* by drinking mineral-deficient water, even if the diet is good. And we don't merely avoid becoming depleted by drinking mineral-rich water: many nutritional deficiencies can be *corrected* by drinking water containing small amounts of potent, dissolved minerals—electrolytes—which carry the vital electrical charge that allows cells to function.

Simply put, even small amounts of ionic minerals help the body absorb and utilize whatever else you're eating and drinking. People who are sick suffer from an electrolyte imbalance, which impairs digestion. Impaired digestion prevents the body from optimally extracting minerals from food—which in turn impairs digestion even more. It's worth reiterating the WHO researchers' emphasis that "even the relatively low intake of the element in drinking water may play a relevant protective role. This is because the elements are usually present . . . as free ions and therefore, are more readily absorbed from water compared to food where they are mostly bound to other substances."¹⁸ "Iodine, selenium and magnesium," advises *Acres USA*, a holistic farming magazine, "are the three minerals most likely to be deficient."¹⁹

The WHO report also affirmed the danger of "possible increased dietary intake of toxic metals."²⁰ In the absence of beneficial minerals that it truly needs, the body is so starved that it will grab an element *relative* with chemical *similarities*—even if it's a toxic heavy metal. Thus, there are many reasons to make sure the water you're drinking contains enough of the right kind of minerals.

Donaldson explicitly addresses the harm of distillation and any other water purification process (such as reverse osmosis) that either entirely strips the water of minerals or even simply decreases the levels of minerals:

Studies showed that low mineral water caused an extra loss of sodium, chloride, potassium, magnesium, and calcium ions from the body. *Low mineral water isn't neutral, but it pulls out minerals from the body.* So, instead of adding an extra 40 mg of magnesium and an extra 100 mg of calcium from the water, *a person drinking distilled or RO [reverse osmosis, another demineralization process] water will have to make up that much and more, due to the extra loss of minerals. Over time this could have an impact. Not everyone will be affected, but people drinking larger amounts of water or getting fewer minerals from their foods will be impacted first.* . . .

Distilled water can be used if you make up for it with a high mineral intake . . . Distilled water, and other low mineral water, is not a neutral water; it actually takes away from you, whereas water with optimal concentrations of minerals in it actually supply your body with good building material. [emphasis added]²¹

The warnings are very clear. If you drink either low-mineral water or no-mineral water—without compensating for the loss of those minerals by drinking fresh vegetable juices or taking ionic mineral supplements—you *will* damage your health! (For those who may not benefit enough from electrolytes, I discuss specially bound minerals in **Nutritional Supplements**.)

There's one more aspect of distilled water to consider: the equipment used to make and store it. Most commercially available distilled water (which is typically sold in supermarkets and grocery stores) is stored in soft plastic. This is a very poor choice of packaging because the resins of the plastic leach (outgas) into the volatile distilled water (see Insert, "The Dilemma of Plastics and Bottled Water"). If you use a lot of distilled water—which you will, especially if you make your own colloidal silver (see **Colloidal Silver** later in this chapter)—you will save money and have better health if you buy your own distiller. Home units usually come with containers of relatively stable, hard plastic, which although not perfect is much safer than softer plastic. I have not yet found distillers that come with glass containers.

The commercial distillers (which is most units on the market) that cannot eliminate hydrocarbons or volatile

The Dilemma of Plastics and Bottled Water

Plastic is convenient for water storage and it doesn't break. However, it's not biodegradable. Plastics are designated with recycling code numbers inside triangular symbols on the bottom of the containers.

- ◆ **Plastic #1.** Polyethylene terephthalate (PET or PETE), also called *phthalates*. Used for foods, juices, and mouthwash. Plastic is for one-time use only because bacteria readily accumulate on its porous surface. When exposed to heat over long periods, these plastics leach out antimony, a toxic heavy metal.
- ◆ **Plastic #2.** High-density polyethylene (HDPE). This hard opaque plastic is used for drinks, detergents, and some toys. It leaches estrogenic chemicals.
- ◆ **Plastic #3.** Polyvinyl chloride (PVC). Mixed with phthalates to make it soft and flexible, it's used for cling wrap, shower curtains, inflatable toys, flooring, and car interiors. It outgases toxins, causing cancer, immune malfunction, hormone disruption, birth defects, and behavioral and learning disorders.
- ◆ **Plastic #4.** Low-density polyethylene (LDPE). Clear or opaque, flexible but breakable, it's used for drink cartons and food bags. It leaches estrogenic chemicals.
- ◆ **Plastic #5.** Polypropylene (PP). Used for food containers, it's resistant to heat and moisture. PP is hazardous during manufacture but of all the plastics, leaches the fewest dangerous chemicals.

Most plastics are very dangerous. The bottles leach estrogen-like phthalates into the water, feminizing the males of many species including humans. Phthalates are carcinogenic and cause birth defects. They damage the nervous, respiratory, and reproductive systems. Tiny plastic particles, microplastics, leach from bottles into the water—two times more than what's in tap water.

Many products, including canned foods, contain highly toxic Bisphenol-A (BPA), a synthetic carbon-based compound. As more studies have been published on the harm of plastics, consumers have demanded safer substitutes. In response, the plastic bottle industry has changed many of its formulas. But although BPA is no longer being used in many items, it's now being replaced with Bisphenol-S (BPS). Bisphenol-S is touted as safer, but researchers are finding that it causes at least as much damage as—and probably more than—BPA.

It takes precious resources, energy, and petroleum to manufacture bottles. It also seems wasteful to ship countless brands of water from halfway across the world. And, despite the recycling imprints on the containers, much of the plastic is *not* recycled. Plastics end up in our waterways, destroying the habitats of ocean dwellers from corals to sea turtles to whales.

Marine mammals, caught in plastic debris, drown and die in the sea, unable to surface for air. The situation is so serious, Japanese scientists are trying to further develop a type of bacteria that they discovered feeds on plastic.

Bottled water is subject to heavy marketing fraud. Corporations that are losing money from reduced soda sales are trying to regain income by selling "designer" water that they falsely advertise comes from "clear, pristine mountain streams" or "untouched melting glaciers." A very few bottled waters, which do taste wonderful and feel vibrant, have (truthful) labels indicating a high mineral content and a correspondingly alkaline pH. Too often, though, the claims of water bottlers are bogus. Their designer water is simply tap water that has been filtered—and not very well. Most brands show high levels of contaminants, including bacteria, arsenic, chloroform, phthalates, and microplastics. Bottled water is rarely thoroughly tested.

Forgetting the very real problems of unsafe plastics and environmental destruction (both in the creation and discarding of the bottles), it's disturbing that consumers' desire for bottled water is automatically considered a "fad." If tap water tasted that great—or was as healthy or innocuous as some claim—there would be less consumer demand for bottled water. I have *never* found tap water to be drinkable. One house I lived in had sulfur in the water, which came directly from an underground well. Sulfur is great if you're soaking at a hot spring: the water heals the skin and relaxes muscles. But most people find sulfur thoroughly unpalatable for internal use. In another dwelling, my water came from an underground spring, but it was heavily chlorinated and fluoridated before it reached the sink. In Philadelphia, one of the largest cities on the East Coast of the US, the municipal tap water was subjected to so many harmful chemicals that the water literally foamed as it came out of the kitchen faucet! And in a country home I rented for awhile, the pH was much too acidic for me, at 5.5.

Clean water isn't a privilege, it's a right. However, tap water isn't drinkable. And plastics are unsafe, wasteful, fraudulently marketed, and destructive to the environment. Many good brands of silicone-coated, reusable glass containers are now being sold. You can fill them each time with clean water—filtered and mineralized, or electrolyzed—before you leave your home. It's more work, but safer for all life.

Contamination and taste of water wouldn't be an issue if the water were filtered and ozonated. Ozone is the safest, most effective way to purify water.

organic compounds (VOCs) such as benzene, boil and condense the water only once. A few of the better units are equipped with a second filter. This additional filter further sanitizes the already distilled steam, and will remove almost all of the hydrocarbons. This is a great advantage for those whose water is filled with such contaminants. Fairly good quality water distillers can be bought for just over a hundred dollars. Units that put the steam through an additional cycle to remove most of the hydrocarbons, cost more.

Distilled water does have its place, as long as you compensate for its disadvantages and remineralize the water after cleaning it. Adding minerals to clean water that's not even distilled is also a good idea. After discussing reverse osmosis and water electrolysis, I will suggest ways in which you can remineralize your water.

Reverse Osmosis

Many homes in the United States use a filtration system called *reverse osmosis*, or RO. This US government-funded technology was developed in the late 1950s to remove salt from sea water. First used by industry (including water bottling plants), RO eventually became available to consumers. It can be installed at the main water line that feeds the entire house to be used for drinking, clothes and dish washing, and bathing. Or, smaller units can be installed under the kitchen sink to treat drinking water only, and still smaller units can be placed on a countertop.

During the RO process, water is forced at high pressure through a series of coiled, semipermeable membranes, which separates the water from unwanted substances. As with all types of water purification units, RO filters need changing because bacteria accumulate over time. RO has some advantages. Unlike most other filtration processes, it eliminates fluoride. It also diverts the waste materials into a drain, thus slowing contaminant buildup in the units themselves.

There are, however, some disadvantages to most RO systems. They waste four gallons of water for each usable gallon collected. And the water can taste awful, probably due to its lack of minerals. Any minerals that RO normally removes are larger than the water molecules—minerals that the body can't assimilate anyway. But if the treated water contains no assimilable minerals (electrolytes), the water acts like distilled and leaches molecules of insoluble metals from the plumbing pipes or metal in the unit, imparting a metallic taste to the fluid. There are exceptions, however. One affordable countertop RO system that produces great tasting water, and yields more water than it wastes, is AquaTru (see Appendix A).

Water Electrolysis (Ionization)

Most people have not heard the term *electrolysis* used in relation to water. (Its popular usage pertains to the removal of hair.) Water electrolysis, also called *ionization*, was developed in Japan several decades ago. This wonderful way of treating water is worth exploring in some depth. Although water electrolysis involves learning just a bit more chemistry, because so many people benefit from this technology it's worth trying to understand it.

As already discussed, when ions are present in a liquid, electrical energy can be conducted through the solution. In a liquid, different elements form ions in varying amounts, depending on the ability of the atoms to gain or lose electrons. These atoms *dissociate* or *ionize* in solution to form either *hydrogen* ions (H+) or *hydroxyl* ions (OH-). Depending on the presence or absence of H+ and OH- ions, a given solution will be acidic or alkaline. If the hydrogen ion (H+) concentration is *higher* than the hydroxyl ion (OH-) concentration, the material is *acidic* (as in "acid"). If the hydrogen ion (H+) concentration is *lower* than the hydroxyl ion (OH-) concentration, the material is *alkaline* (or *basic*, as in "base"). Put another way, if there are more hydroxyl ions (OH-) than hydrogen ions (H+), the liquid will be alkaline.

Minerals tend either to be *positively* charged or *negatively* charged. Some common acidifying minerals are iodine, sulfur and phosphorus. Some common alkalizing minerals are potassium, sodium, calcium, magnesium, iron, lithium and manganese. The presence of acidic minerals (which tend to have a negative electrical charge) corresponds to positively charged H+ ions. The presence of alkaline minerals (which tend to have a positive electrical charge) corresponds to negatively charged OH- ions.

During water electrolysis, the two opposite-polarity ions, OH- and H+, are created when an electrical charge is passed through the water. Then an elaborate dance begins. Sang Whang, an enthusiastic proponent of water ionization, explains:

Alkaline minerals in the positive electrode chamber migrate into the chamber with [the] negative electrode; the positive electrode repels positive charges and the negative electrode attracts positive charges. As these positively charged alkaline minerals enter the negative electrode chamber, they combine with hydroxyl ions (OH-) in H₂O, kicking out hydrogen ions (H+). These hydrogen ions then travel to the negative electrode and give up their positive charge and become electrically neutral hydrogen molecules (H₂).

How Does Alkaline Water Behave Once It's In the Body?

When the alkaline water reaches the very acidic stomach, doesn't the stomach's hydrochloric acid neutralize it so that the water is no longer alkaline? If so, what's the advantage of drinking alkaline water?

The pH of alkaline water indeed becomes more acidic in the stomach, while at the same time the normal 4.0 (acidic) pH of the stomach fluid becomes more alkaline. Yet the alkaline water is not wasted. Its minerals are used by the body to maintain the correct pH of the tissues, which is a vital job.

Alkaline minerals reaching the stomach react with the hydrochloric acid to form alkaline compounds: chlorides; carbonates; and magnesium, potassium, sodium, and calcium bicarbonate. These bicarbonates travel to the small intestine to neutralize the acidic food slurry (*chyme*) exiting the stomach. Neutralization is necessary because the intestine doesn't possess a thick layer of mucus to protect its walls from the corrosive food mixture. The pancreatic juice made by the pancreas, which also mixes with chyme, contains sodium bicarbonate for the same reason.

Some of the sodium bicarbonate made by the body goes into the blood. If too much acidity threatens the bloodstream—blood pH should be between about 7.35 and 7.45 at all times—the sodium bicarbonate acts as a buffer to make the pH more alkaline. It creates the buffer by dissolving solid acidic wastes into liquid. This releases carbon dioxide, which is expelled through the lungs. (Likewise, if the blood threatens to become too alkaline, acidic buffers appear to make the pH more acidic.)

Gauging by the pH value of the stomach alone, one might wonder if alkaline water ever reaches the body. But it does. All minerals are transported to the extracellular fluids, which surround each cell of the body. Naturopathic-chemist Frank Cuns-Rial explains:

The extracellular fluid is the largest and most disregarded organ of the body. The blood deposits nutrients into this fluid, and from there the nutrients are transferred into the cells. The health of this fluid is paramount because it interacts with the blood and the cell membranes. It's important to have a wholesome concentration of alkaline minerals to feed the cells and influence the blood pH.

Minerals are bound or attached to different chemical combinations or compounds, resulting in chlorides, carbonates, etc. These combinations perform different tasks as required by the body. For example, an atom of magnesium might exist in the form of a chloride in the stomach, as aspartate [a

compound of aspartic acid] in the gut, and as citrate once it reaches the cell membrane. When magnesium finally enters the cell, it's ionic, or unattached, with a minute electrical charge. Sometimes the mineral is strongly linked (as in the chloride form). Sometimes it's loosely linked (as in the aspartate form). And sometimes it's very loosely linked to other substances such as enzymes, proteins, or hormones. But the atom itself does not undergo any chemical change when it's attached to different carriers. Ultimately, it's the ionic form of the mineral that confers alkalinity to the extracellular fluid.²²

In other words, although minerals often can (and do) change from one chemical form to another, their *intrinsic identities* remain intact. Therefore, an inherently alkaline mineral—no matter how it's bound, what other compound it's attached to or how it's "packaged"—will maintain its inherent alkalinity. It will impart that inherent alkalinity to the extracellular fluid. This is why alkaline water maintains its alkalinity at the cellular level.

Optimally, one should drink alkaline water on an empty stomach. The stomach is designed to produce more hydrochloric acid as soon as its pH rises above 4.5. Therefore, when alkaline water with an 8.5 pH or higher is drunk, the stomach produces more hydrochloric acid—which, in turn, increases the body's production of bicarbonates, which then enter the bloodstream.

Alkaline water proponent Sang Whang believes that one major cause of aging is due to insufficient levels of bicarbonates in the blood. Less bicarbonate means a reduced ability to neutralize and eliminate acidic wastes produced by the body. The phrase "alkalize the system," Whang points out, does not refer to raising the pH of the urine or saliva—remember, the blood pH is regulated to remain constant—but to increasing the amount of bicarbonates in the blood. Significantly, when all aspects of the body's pH are balanced, the tissues are oxygenated at their saturation point, which reduces the possibility of cancer and other diseases.

While many people feel better drinking alkaline water, not everyone benefits. Some people are helped, but only for brief periods. Depending on the water source, an optimal pH for water may range from about 6.5 (if it's from a living spring, producing clustered water) to 8.5. If you have concerns about drinking alkaline or acidic water on a regular basis, consult with an experienced specialist who understands body chemistry and your unique health issues.

The opposite process takes place with acid minerals. Acid minerals migrate into [the] positive electrode chamber and combine with hydrogen ions (H^+) in H_2O , kicking out hydroxyl ions (OH^-). These hydroxyl ions then travel to the positive electrode, lose negative charge and become water (H_2O) and oxygen (O_2). In the ionizer, oxygen gas is released from the acid water chamber and hydrogen gas is released from the alkaline water chamber. Both chambers remain electrically neutral.²³

Simply put, a water electrolysis unit (ionizer) converts regular tap water into alkaline water and acid water by separating the acid-forming and alkaline-forming minerals via an electrical current. Negatively charged minerals are attracted to the positive electrode, and positively-charged minerals are attracted to the negative electrode. During this process, the acidic ions and alkaline ions are also separated and eventually neutralized. What remains is water called “acidic,” which contains acidic minerals, and water called “alkaline,” which contains alkaline minerals. The acidic and alkaline waters are collected in two separate chambers attached to separate output tubes.

Depending on the mineral content of the source water and the pH programming of the ionizer, the pH value of the alkaline water can range anywhere from the low 7s to 10.5 or even higher. Whang writes:

The main alkaline minerals of tap water are calcium and a small amount of magnesium. . . . In the pecking order of ion exchange of the four alkaline minerals in water, potassium is the strongest, next is sodium, then calcium, and the last is magnesium. Stronger minerals can replace weaker minerals, but not the other way around.²⁴

Perhaps even more important than the pH modification, this unique water technology also changes the molecular structure of the water—usually from a 12-molecule cluster into a hexagon, half as large as tap water molecule chains. Such water more completely dissolves those minerals that are present. The smaller molecule also makes water “wetter,” able to permeate cellular membranes more easily and rapidly. This superior hydration promotes more efficient nutrient transport across the cell membrane, and a more complete removal of wastes. Sometimes wetter (ionized) water is called *micro-clustered* or *clustered* water.

Both acidic and alkaline waters have been successfully used in Japanese hospitals for many years. The skin—whose natural, slightly acidic coating acts as a protective barrier against germs—is bathed in the acid water for treatment of skin conditions such as eczema and boils.

When people drink the alkaline water, the internal pH becomes more balanced, and the body’s terrain becomes less hospitable to pathogens. Alkaline water has a higher concentration of oxygen as well as assimilable minerals.

The degree of benefit from water electrolysis (ionization) depends on the source water feeding the unit. If your goal is to obtain large quantities of alkaline water, your source water must be sufficiently alkaline. If the water is acidic—say, below 6.8 or 6.7 (7.0 is neutral)—you’ll have to pump quite a bit of water through the device to obtain enough alkaline fluid for drinking (although you’ll get lots of acid water for a refreshing bath). Also, even if the finished water product is purified and contains only ionic (assimilable) minerals, these minerals might not exist in the proportions that your body needs. An electrolysis device can only work with the minerals present in the source water. For this reason, some units are equipped with calcium and magnesium mineral packets that add alkalinity (and those particular minerals) to the water.

Do you need a water electrolysis unit if your source water is substantially alkaline, and contains a nice variety of minerals in the amounts that you need? That depends. Even though water is an excellent solvent, not all of the minerals in it may be completely dissolved (ionic). Over time, mineral salts that cannot be dissolved (and are thus unable to be assimilated) can cause damage similar to that of heavy metals. They can lodge intrusively in the joints (causing arthritis) or remain in the kidneys (causing painful stones that block the ducts). This is the one way in which beneficial minerals can act like heavy metals: if they aren’t absorbed by the body. For this reason alone, some people invest in a water electrolysis unit.

Restoring the Water

Now that you have purified your water (without using chlorine or other toxic chemicals), the solution may be low in minerals, depending on the method used. What can be used to remineralize your water?

There are many brands of ionic minerals (sometimes called *colloidal minerals*) on the market, small amounts of which are mixed into large quantities of water. The best quality products contain minerals that are not only found in large amounts (such as magnesium), but also trace amounts. Trace minerals, although required in minute amounts by the body, are essential for cellular function and overall health.

Some liquid mineral preparations also contain *fulvic acid*, a fluid created by beneficial bacteria that live at the roots of plants. Fulvic acid dissolves soil minerals and converts them into their simplest ionic forms. This makes the minerals more bioavailable, easily entering the

cells of plants, animals and humans. Hence, fulvic acid's reputation for increasing oxygen absorption, decreasing systemic acidity, improving enzyme activity, stimulating immune function, and assisting in carbohydrate and protein metabolism. The ancient Ayurvedic medicine system from India offers a tarry, gooey preparation called *shilajit*, which has been used for centuries to improve health. It contains large amounts of fulvic acid.

Willard's Water is a safe and non-corrosive fluid added to regular water. It contains sodium metasilicate, calcium chloride, magnesium sulfate, sulfated castor oil, and soluble lignite. These ingredients slightly change the angles in the water molecules, giving the solution a lower surface tension and making it "wetter." With an alkaline pH of about 8.7, Willard's Water stimulates plant growth and helps restore tissue function in humans and animals. For those who enjoy electronics, the Cell Wellbeing Hydration App, downloadable onto an ordinary cell phone, produces a similarly clustered water that makes drinks taste better. (Details on both are in Appendix A.) Clustering and minerals accompany each other in restored water.

It can take some time to heal from the effects of electrolyte starvation. *If you do decide to distill your water, make sure to liberally supplement your diet with minerals*, many of which may be more bioavailable as liquid electrolyte formulas than as capsules. The most "alive" water moves swiftly over rocks and receives at least some sun, so you can emulate this process. Energize your water

by pouring in liquid minerals, placing the container in the sun for at least an hour, and then shaking the container. The shaking helps restore the electrical charge, especially if it makes the mineral particles smaller. Once the water is saturated with organic minerals, light and movement, it's no longer de-natured (distilled), but revitalized with the qualities of living water. You can use this technique to benefit other types of water as well. Sunlight, movement and electrical charge never hurts!

Incidentally, water from different locations is different not only in function but also structure. See Sidebar, "The Structure of Water."

How Much and How Often?

Many people don't drink enough water. Susan Kleiner, who is considered an expert on water, writes:

A portion of the population may be chronically mildly dehydrated. . . . Dehydration of as little as 2% loss of body weight results in impaired physiological and performance responses. . . .

Early signs of dehydration include headache, fatigue, loss of appetite, flushed skin, heat intolerance, light-headedness, dry mouth and eyes, burning sensation in the stomach, and dark urine with a strong odor. Signs of more advanced, severe dehydration include difficulty swallowing,

The Structure of Water

Does structure relate to function, as many natural scientists assert? Japanese photographer Masaru Emoto decided to find out if this were true of water. He wrote: "The Earth is called the 'Water Planet' and about 70% of its surface is covered in water," just as human beings consist of about 70% water. "If water is contaminated, all creatures would be denied . . . existence. Considering these environmental situations, I continued to seek a way to clearly evaluate water. . . . What is the difference in the information that each kind of water holds?"²⁵

Knowing that snow crystals always form lovely, symmetrical, and quite elaborate embellished hexagon shapes, he took water from different locations, froze individual drops, and then—at a specific melting point similar to the temperature under which snowflakes form—photographed the crystals through a microscope. The result is a fascinating book, *The Message from Water*, which shows the reader photographic proof that the molecular structure of water is determined by its source and treatment.

Emoto obtained water samples from all over the world. These included Japanese mountain streams, a New Zealand glacier, the London municipal water supply, tap water from the northwestern United States, and a French fountain in Lourdes known for its healing properties. Water from scenic, tranquil locations always had perfectly symmetrical, beautiful, crystalline designs. Their colors were generally white or gold, and they were always bright. Moreover, their six-sided shapes were embellished with elaborate branches—some of them feathery, some more bold. Polluted industrial water, water from pipes and storage dams, and stagnant water always exhibited chaotically formed, ugly, misshapen structures. Their colors were dark brown and gray, and they were always dull.

Living water is geometrically balanced, with correspondingly balancing effects on the body. Contaminated water is geometrically *imbalanced*, with *unbalancing* effects on the body. Interestingly, although distilled water is not contaminated, its pattern still differs markedly compared to all the other uncontaminated waters tested. Distilled has the most simplistic pattern, consisting of an unembellished, straight line hexagon without any lovely symmetrical branches. It's as though the hydrogen and oxygen are missing something (which they are): minerals!

clumsiness, shriveled skin, sunken eyes and dim vision, painful urination, numb skin, muscle spasms, and delirium. . . . New research indicates that fluid consumption in general and water consumption in particular can have an effect on the risk of urinary stone disease; cancers of the breast, colon, and urinary tract; childhood and adolescent obesity; mitral valve prolapse; salivary gland function; and overall health in the elderly.²⁶

The health conditions that can result from dehydration are not surprising, considering the role that water plays in the body. Water is so important that the late medical doctor Fereydoon Batmanghelidj (bat'-man-ge'-lij) wrote *Your Body's Many Cries for Water*, a well-documented book devoted entirely to the topic. The idea for the book began during a politically-motivated incarceration in the Middle East, where Dr. Batmanghelidj was the only one present to provide medical services to his fellow prisoners. With no medical supplies available to him, he had only plain water to treat a man suffering from ulcers. Not knowing what else to do, Batmanghelidj administered the fluid in systematically timed, very small amounts. To his great surprise, the man's pain completely vanished. This inspired Batmanghelidj to investigate the healing properties of ordinary water—which for him, was from the tap.

Dr. Batmanghelidj's advocacy of tap water caused great confusion with many American readers, whose experience with municipal (tap) water is a toxic brew of chlorine and other chemicals. When I telephoned the doctor's office to inquire about this, his wife explained to me that Dr. "Batman," as most people affectionately called him, defined "tap" water as clean and drinkable, free of contaminants and apparently full of ionic minerals—the kind of water he grew up with in his native country. Mrs. "Batman" also volunteered that the doctor felt that the US government had failed in what he saw as its mission: to cherish and protect our water, which is every person's right to enjoy.

Knowing that the municipal tap water of which Batmanghelidj spoke was clean and mineralized, we can understand why he repeatedly stated that plain tap water is quite sufficient to induce the many remarkable recoveries from illness that he observed over the years. Nearly all of

the symptoms we regard as disease—symptoms that are diverse, numerous, and localized differently according to who is experiencing them—are the body's normal responses, Dr. Batmanghelidj asserted, to *dehydration*. When the body lacks sufficient water for its many vital functions, a kind of "drought management" takes place: *histamine*, a neurotransmitter, allocates water to those systems that need it the most. Because digestion is a primary life-sustaining function and can only occur with adequate saliva, the mouth is one of the last places in the

body to be deprived of water. (The digestion of starch and sugar begins in the mouth, and we additionally need saliva to swallow the food.) Thus, the dry mouth ordinarily associated with the need to drink is actually the *last* indication of dehydration.

Histamine is also responsible for directly or indirectly producing the bodily responses and sensations we call illness: sinusitis, asthma, allergies, and even chronic pain. These sensations indicate that certain

areas of the body have been deprived of needed water because the small amount of water that *is* present is needed for other, more vital functions. Batmanghelidj gave convincing proof that dehydration is also heavily implicated in colitis, diabetes, hiatal hernia, high blood pressure, and other illnesses. The list seems endless.

Initially, Batmanghelidj was either ostracized or ignored by most of his colleagues. However, he received notes from people all over the world thanking him for helping them restore their health through this simple but vital practice. Dr. Batmanghelidj sold only books. He never advocated or sold drugs, supplements, or bottled water. Mrs. "Batman" continues his work today.

Not all health specialists agree that drinking water is essential. Some believe that we should "eat" our water in the form of 70% high-water-content foods—in other words, a diet consisting largely of fruits and vegetables. However, not everyone can consume enough high water-content produce to meet their daily water consumption requirements. Even if processed, concentrated and dried foods are avoided, people who are ill or partly dehydrated may be too debilitated for the body to easily extract the badly needed water from food.

How much water, then, should one drink? Opinions vary. One recommendation is six to eight glasses of water per day; more if there's strenuous activity, high

Just A Few Signs of Insufficient Water Intake

- ◆ Thirst
- ◆ Hunger, even after having recently eaten
- ◆ Allergies to foods and other substances
- ◆ Fatigue
- ◆ Mood swings, confusion and anxiety
- ◆ Pain in back and joints
- ◆ Skin dryness or wrinkles
- ◆ Digestive disorders, including constipation
- ◆ Infrequent and/or dark colored urine

temperatures, or a diet heavy in salt. Another guideline is one fluid ounce for every two pounds of body weight. This would make two quarts sufficient for a person weighing 128 pounds, 2½ quarts for someone weighing 160 pounds, and so on. But this formula may not work for people weighing more than 200 pounds, as even the healthiest person can die of a mineral salt (electrolyte) imbalance. To compensate for the danger of overly diluting the body's electrolytes, Batmanghelidj had advised replenishing the mineral salts daily lost through urination. (The type of

salt is important; see Sidebar, “Real Salt—More Than Just Sodium Chloride.”)

A European woman once asked me why Americans drink “so much” water. This is probably due to the overemphasis, in the typical diet, on concentrated, carbohydrate-rich foods such as bakery products and chips, and the scarcity of high water content vegetables and fruit. The omission of fresh produce creates the need to drink more (although someone who's sick shouldn't be eating chips and similar foods anyway). Most health practitioners

Real Salt—More Than Just Sodium Chloride

In March 1930, lawyer, peace activist, philosopher, and future Nobel Prizewinner Mahatma Gandhi led a 239-mile (385-kilometer) march across India to protest the British tax on salt. The non-violent resistance leader and other marchers were brutally beaten and arrested by the police. Eventually, the protesters helped to eliminate the tax on salt as well as secure India's independence from the British.

Why did the protestors risk physical injury and worse? It wasn't just for national independence. They recognized the value of salt. Salt is critical for life. It assists in brain development. It aids digestion: the chloride in sodium chloride is used by the body to make hydrochloric acid, needed for protein utilization. Salt helps overcome adrenal exhaustion. It allows nutrients to enter the cells and waste materials to leave. Sea water is almost identical in composition to that of human blood. From the beginning of history, humans have instinctively gravitated toward a food that contains all of the minerals in the body. No civilization can develop without salt.

What passes for salt almost everywhere is adulterated. Real salt grows in a crystal shape, sometimes as large as one millimeter. The crystalline particles harvested from the sea contain almost one hundred trace minerals, including calcium, boron, magnesium, gallium, germanium, gold, lithium, manganese, molybdenum, potassium, selenium, silicon, silver, sulfur, vanadium, and zinc. When trace minerals exist in sufficient quantities, the relatively large amounts of chloride and sodium in a salt crystal are beneficial. In *Seasalt's Hidden Powers*, Jacques de Langre explains how commercially processed salt is stripped of its valuable trace minerals:

Because table salt comes from the same batch as vacuum-refined industrial salt, it is treated with caustic soda or lime to remove all traces of magnesium salts. These vital magnesium salts are taken out because they keep the salt from flowing out of the dispenser spout. . . . [This practice brings] more profits [to] the chemical market. Yet these magnesium salts . . . fill important biological and therapeutic roles. Further, to prevent any moisture from being reabsorbed, salt refiners now add alumino-silicate of sodium or yellow prussiate of soda as dessicants, plus different bleaches to the final salt formula. But since table salt, chemically treated in this way, will no longer combine with human body fluids, it invariably causes severe problems of edema (water retention) and several other health disturbances.²⁷

The dictionary defines *prussiate* as “a salt of prussic acid; cyanide.”²⁸ It's shocking that a recognized poison can be so cavalierly added to one of our most common foods.

Even if salt is not contaminated by toxic foreign chemicals, the processing (refining) alone renders it useless because it's stripped of valuable minerals. This includes industrial salt, presumably edible grocery store salt, and even most “sea salt” sold in health food stores. Any salt that's dried by intense heat and then re-crystallized, has no vitality or nutritive value. Ironically, people who work for commercial salt companies are very proud of the “purity” of their denatured salt. They don't understand that denatured salt is not a real food.

When salt is isolated from its matrix, the body instinctively knows that something is missing. This explains why it's easy to binge on an entire bag of salted potato chips, pretzels or corn chips. It's not only the carbohydrates that are addictive. So is the incomplete salt: we seek the minerals that were removed during processing. Continuing to eat ordinary commercial salt causes even greater mineral depletion, which then creates more cravings.

Our fondness for salt is a normal biological need. (Note that animals in nature gravitate toward salt deposits to lick them.) What is abnormal is the white synthetic crystals that the commercial food industry promotes as real. Denatured salt has been linked to a number of diseases, including high blood pressure and heart attacks. Several salts are now on the market in their unaltered crystalline form. Some favorites are Celtic sea salt from France (which closely matches the body's mineral content), and pink salt from Hawaii and the Himalayas.

agree that drinking water each day is important, separate from the increased needs that the use of Rife Therapy creates. Of course, one shouldn't consume too much water, too quickly.

The problem with any guidelines is that they don't always pertain to everyone. Just as there is no one-size-fits-all diet (discussed later in the **Food** section), there's no one-size-fits-all requirement for water. For instance, someone with a lethargic lymphatic system does not handle fluid elimination as easily as someone with a more efficient system. Sandra Cabot, an Australian medical doctor and naturopath, classifies individuals who tend to retain water as *lymphatics*:

Fluid retention occurs because the return of blood through the veins in the arms and legs back to the heart is sluggish due to weak valves within the veins and poor muscle tone in the limbs. Fluid also tends to accumulate in the subcutaneous tissues between the skin and the muscle layer because of an inefficient lymphatic system.²⁹

With poorly working lymph channels, not only is water trapped between the tissue cells, but the electrolytes (and also water-soluble vitamins, including B vitamins) become diluted and are present in the wrong ratios to each other. This, in turn, causes even more edema (water retention). (See **Exercise** later in this chapter for more information on the lymphatic system.) Lymph plays such an important role in immune response that its inefficiency makes one more prone to swollen glands, excessive mucus production, allergies, sinusitis, hay fever, bronchitis, and asthma. Thus, it's important to pay careful attention to water intake, especially when rifeing. Sufficient water is required to flush out harmful microbial toxins, but too much fluid can cause bloating. Everyone is different, and will have to determine his or her own comfort and health level. Bloating from water intake may indicate electrolyte imbalance, insufficient nutrition, kidney dysfunction—or, simply an intake of too much water. Adding a liquid electrolyte supplement, plain lemon juice, or good quality salt to your water can help reverse the bloating.

Whether you require a large or small amount of water daily, or an amount in between, consider following Batmanghelidj's guidelines on *how* you drink. The bloodstream can only handle being diluted by about four ounces of water every half hour, as the kidneys immediately filter the excess to maintain the fluid balance of the blood. Therefore, sip water in small amounts—8 ounces per hour as the upper limit, and 4 ounces per half hour as the ideal.

Healthy Additions to Plain Purified Water

Vitamin C

If you want a zippier taste than what liquid electrolytes provide, try Vitamin C. Vitamin C helps eliminate excess fluid, makes the water more absorbable, and protects against infection by strengthening the cell membranes, thus making viruses less able to penetrate. The minimum daily requirement of Vitamin C established by the US government is much too low. The bodies of most mammals can produce Vitamin C, but not humans. We are dependent on external sources for our supply.

Most Vitamin C is sourced from corn, and most corn is genetically modified (discussed later in this chapter); however, some Vitamin C is made from cassava. The Vitamin C Foundation (vitaminfoundation.org) recommends sources of clean ascorbic acid. Some food-based powders contain Vitamin C and bioflavonoids (see **Nutritional Supplements** later in this chapter). An underappreciated source of Vitamin C, with its related bioflavonoids, is rose hips. Rose hips are commonly sold as a tea, but even moderate heating destroys the delicate bioflavonoids. It's better (and more economical) to purchase rosehip powder in bulk, and mix it in room-temperature (not boiling) water to make a delicious beverage. Sprinkled onto food, rosehip powder imparts a wonderful sweet and sour taste to stews and desserts.

Lemon Juice

Freshly squeezed lemon juice is high in Vitamin C and can help eliminate nausea, which you may experience if you're on a detox program. Even more important, advises psychiatrist and electromedicine expert Dr. Steve Haltiwanger, lemon juice raises pH levels that are too low and lowers pH levels that are too high. Lemon also cleans the receptor sites of the cells, allowing them to take in nutrients along with the biochemical messengers (including hormones) that the body produces. Squeeze some lemon juice into your drinking water and drink it within 30 minutes, as its Vitamin C loses potency.

Baking Soda

If you can handle the addition sodium, dissolve half a teaspoon of baking soda (sodium bicarbonate) into a gallon of water to alkalize it. Drink it at least an hour before or two hours after a meal, as you don't want to dilute the stomach acids that are needed for digestion.

Chlorophyll

Produced by green plants, chlorophyll is an excellent blood builder and strengthener. See **Popular Beverages and "Health" Drinks**, next page.

Highlights

Get your water tested every one to two years, both before and after filtration (or purification or electrolysis). This will tell you the source water's quality, how well your unit is working, and if the final water meets your needs. Testing your source water will also help you decide what type of water processing unit to get—or if a wiser choice is to buy spring water. Does your water contain pathogens, chlorine or other chemicals, heavy metals, undissolved minerals, or other contaminants?

Properly mineralized water has a subtle sweet taste, and is very refreshing. Your drinking water needs to contain minerals. If you don't have access to a pristine mountain spring or well, acceptable substitutes are:

- ◆ Distilled water (ideally, that you distill yourself), to which you add an appropriate electrolyte formula. You can also shake it and expose it to sunshine.
- ◆ Water that is first filtered for pathogens, chemicals and other contaminants, and is then mineralized. A good electrolyte formula and Willard's Water add minerals and also raise the ORP of the water. Fresh squeezed lemon juice is always a good choice.
- ◆ The water you drink may make the difference between poor health and vitality. *If you are rifting, it's very important to replenish your mineral supply.* The body uses up a lot of minerals when you are detoxifying and eliminating pathogens. This is addressed in more detail in Chapter 4.

POPULAR BEVERAGES AND "HEALTH" DRINKS

People who are ill often ask if coffee, tea, soda, conventionally prepared commercial milk (which is homogenized and pasteurized), hot cocoa, chocolate milk, or fruit juice are comparable to properly mineralized water. They are not! In most cases, these drinks require more nutrients for their assimilation than they give to the body. They also cause dehydration, as they force the body to use its precious water stores to eliminate the wastes they contain and produce. Don't forget that accumulated waste provides a fertile breeding ground for harmful microorganisms. Waste also encourage tissues to degrade. If you are used to drinking lots of coffee, soda or fruit juice, might this be what has sapped your vitality in the first place?

Coffee

Coffee is the most popular beverage on the planet worldwide, amassing \$30 billion a year in sales. What we call the coffee "bean" is actually the seed of a fruit that grows on several species of tropical evergreen trees. The flesh of the fruit is discarded, but the bean is dried, roasted, ground, and brewed into a beverage. Depending on the source, statistics vary somewhat on how many in the US drink coffee, but even the lowest statistics are high. According to July 2006 figures from the National Coffee Association, more than three out of four adult Americans drink coffee regularly or daily. In both 2000 and 2014, figures for the average coffee consumption in the United States have remained a steady 3.1 cups per day, the average size cup measuring 8 ounces or larger. The most recent figures state that 54% of Americans over the age of 18 drink coffee daily. The beverage has a unique, aromatic scent that many find intoxicatingly pleasing, although even some committed coffee aficionados admit that it smells better than it tastes.

Recently, a heated debate has emerged regarding the dangers vs. benefits of coffee. I'll first present the negative data—because not only is it abundant, in my opinion it may have less bias than the positive reports.

Coffee is regarded as an addiction because of its caffeine content. Many people cannot wake up and greet their day without having at least one cup. A so-called moderate coffee drinker is estimated to ingest between 300 and 400 mg of caffeine daily. Caffeine is a legal drug that can harm, and even irreparably damage, the nervous system and adrenal glands. Most people don't know that as we age, the adrenals take over functions previously performed by the sex glands, including the production of various hormones—DHEA, estrogen, pregnenolone, progesterone, and testosterone. It is known, however, that the adrenals are connected to the fight-or-flight response. Let us examine coffee's disruption of this response.

Normally, the adrenal glands secrete hormones in an emergency. To give an oversimplified summary, adrenaline is released during acute (sudden-onset, short-term) stress and cortisol is released during chronic (long-term) stress. When the danger has passed—that is, when there is no longer a reason to fight or flee—the adrenals stop secreting the hormones. But caffeine interferes with adrenal function by causing the *continual* production of cortisol. This elevates the heart rate, raises blood pressure, and abnormally increases respiration. Excess cortisol also causes fat to gravitate to the belly and the neighboring internal organs.

Caffeine influences blood sugar levels by exerting a "domino effect" on not only the adrenals, but also other

organs and glands involved in sugar regulation. The adrenals hormonally signal the liver to release its supply of stored sugar (glycogen) into the bloodstream. In response to this sudden rapid rise in glucose, the pancreas quickly releases insulin to drive the sugar out of the bloodstream and into the tissues. This causes blood glucose levels to drop from too high to too low. Over time, both the pancreas and adrenals become exhausted from these constant, abnormally rapid switches. Tired glands are a huge contributing factor in permanent diabetes and hypoglycemia.

Although the unremitting stimulation from caffeine can exhaust the adrenals to the point of becoming dysfunctional, one might not feel exhausted immediately. On the contrary, many people feel that drinking coffee gives them a much-needed lift. But this stimulation is artificial, due to the temporary rise in blood sugar. Once the blood sugar drops to dangerously low levels, the underlying fatigue is felt. Attempting to recoup waning energy, the person drinks another cup—and the cycle starts all over again. It's no accident that pastries, bread, rolls, cakes and pies are the favorite accompaniment of coffee. Unfortunately, the high amounts of sugar and starch in these foods stress the pancreas even more. This is why many coffee drinkers gain weight. The metabolism-stimulating effect of coffee increases appetite and cravings for sugars and carbohydrates. Any glucose not utilized by the cells at a given time is stored as fat.

Kidney function is also affected. Normally, when urine passes through the kidneys to be filtered, the kidneys recycle minerals that are still needed by the body. But coffee forces the kidneys to excrete vital calcium, iron, magnesium, potassium, and trace minerals—which eventually creates deficiencies in these minerals. Caffeine breaks down into uric acid in the body, which can eventually cause kidney stones and gout.

Caffeine prevents the pineal gland in the brain from producing its sleep-inducing hormone *melatonin*, which is why coffee drinkers may suffer from insomnia. Caffeine inhibits the enzymes used to form memory, eventually causing a loss of memory. And caffeine can cause abnormal DNA by inhibiting the mechanism that repairs it.

Some effects of caffeine are gender-specific. In women, it can aggravate or cause premenstrual syndrome (PMS), menopausal symptoms, and even breast cancer, as well as induce higher rates of miscarriage and infertility. During pregnancy, caffeine crosses the placental barrier. Because fetuses do not have the ability to detoxify caffeine, babies born of women who drink as few as 2 cups a day tend to have lower birth weights, more deformities including cleft palates, heart malfunction, and neurological damage. If the mother nurses, she transmits caffeine and all the other

compounds in coffee to the baby through her breast milk. In men, the irritating caffeine can aggravate prostate problems and urinary tract infections. Both men and women who drink coffee are more prone to osteoporosis.

Besides caffeine, coffee contains more than 208 other acids, all of which bring the pH of the brew to about 5.0 (which is acid; neutral is 7.0). Thus, in some ways, drinking coffee has similar effects as drinking acidic water. The extra burden of acids on the body can cause indigestion and directly contribute to arthritis, rheumatism, and skin disorders.

No one questions that coffee is addictive. Most people who try to quit suffer from headaches, elevated blood pressure, stomach problems, irritability, or other symptoms. Incongruously, some people don't appear to be sensitive to caffeine. They can drink coffee before bedtime and still sleep. However, this may indicate an advanced state of adrenal exhaustion, which ultimately means less resistance to stress and greater susceptibility to illness.

"Decaffeinated" coffee is a misnomer. Decaf still contains 3% caffeine, which is enough to stress your system and cause damage.

One source recommends not to make coffee part of your diet if you suffer from any of the following:

- ◆ Acid indigestion
- ◆ Anxiety, irritability and nervousness
- ◆ *Candida* or yeast problems
- ◆ Colitis, diverticulitis, diarrhea, and other irritable bowel symptoms
- ◆ Chronic fatigue syndrome
- ◆ Autoimmune disorders
- ◆ Diabetes or hypoglycemia
- ◆ Dizziness or tinnitus (ringing in the ears)
- ◆ Gout (elevated uric acid levels)
- ◆ Heart disease or heart palpitations
- ◆ High blood pressure
- ◆ High cholesterol
- ◆ Insomnia and interrupted or poor quality sleep
- ◆ Liver and gallbladder problems, including stones
- ◆ Kidney or bladder problems, including kidney stones
- ◆ Migraines or other vascular headaches
- ◆ Osteoporosis
- ◆ Skin irritations, rashes and dryness

- ◆ Ulcers, heartburn, and stomach problems such as hiatal hernias
- ◆ Urinary tract irritation³⁰

Coffee dehydrates the body. As discussed in the previous section on **Water**, many of the symptoms we regard as illness are the body's response to chronic dehydration. Coffee drinkers also tend to imbibe less water, which compounds the dehydration.

Mastering Leptin discusses the most common signs that you're drinking more coffee than your system can handle: "Caffeine raises blood pressure more than four points [and] contributes to weight gain around the middle . . . This

is because excess sympathetic nerve stimulation causes a numbing effect on fat cells in the abdominal area leading to excess weight gain around the middle. In such situations caffeine is making adrenaline resistance worse."³¹

Despite the massive amount of solid evidence that coffee is harmful in so many ways, positive reports on the brew have recently escalated. One unbelievable claim is that certain compounds in coffee are associated with a decrease in some cancers—which directly contradicts other, more solid evidence that coffee drinkers have a greater risk of developing breast cancer, in part due to the carcinogenic acrylamides formed during roasting (see **Food** later in this chapter.) Another positive report states that caffeine

Coffee as a Pesticide

Federal scientists have discovered that the same chemical that provides the pick-me-up in a cup of java is a deadly turn-off to snails and slugs. Caffeine renders their food unpalatable. Applied to their soil, the stimulant causes snails and slugs to writhe uncontrollably. At the proper dose, these mollusks succumb to the neurotoxin fairly quickly. . . .

Earl Campbell, now with the US Fish and Wildlife Service, and his [Agricultural Research Service] colleagues stumbled on this anti-slug measure while looking for a pesticide to eradicate noisy frogs [in Hawaii]. . . . The species *Eleutherodactylus coqui* has become especially vexing. Its mating calls, which can go on all night—and year-round in low-lying areas—reach 90 decibels, the volume of barking dogs and vacuum cleaners. . . .

After working their way through soaps, surfactants, and off-the-shelf pesticides—all without antifrog effects—Campbell's group started to evaluate products in the grocery store, including acetaminophen (Tylenol®) and cigarette nicotine. "We had very poor results with almost all of these," Campbell told Science News Online. Finally, his team tried a caffeine-rich anti-sleep preparation. . . . It was during early evaluation of caffeine's potential that the researchers applied a dilute concentration of the compound to the soil in greenhouses where many frogs were holed up. At once, Campbell noticed that slugs began surfacing and dying.

That interested [Robert G.] Hollingsworth, an entomologist studying pests of ornamental plants. . . . Small snails have proven a bane to orchid growers [because they] . . . chew away at roots. . . . Hollingsworth launched tests of various concentrations of dilute caffeine against those orchid snails . . . and that local garden denizen, the two-striped slug. . . . The tests showed . . . [that] caffeine makes a good all-natural pesticide. . . .

A 4-ounce solution of 2% caffeine applied to the soil of 4-inch greenhouse pots devastated garden slugs, Hollingsworth found. Within 3.5 hours, 75% of the slugs emerged from hiding in the soil. Within 2 days, 92% of the slugs were dead. When the researchers dropped the concentration of caffeine by half, it took another day to achieve the same body count. When they halved the caffeine level yet again, the kill rate dropped to 55% and the time to death extended to 5 days.

Even concentrations of only 0.1% caffeine may prove useful. Sprayed onto such slug-prized cuisine as cabbage leaves, those concentrations deterred feeding by 62% . . . when compared to uncaffeinated salad greens. This suggests that a regular spray of leftover coffee . . . might control nighttime crop losses in the garden.

Eighteen years ago, Harvard Medical School scientist James Nathanson reported finding that caterpillars would actively avoid eating garden leaves sprayed with caffeine. . . . "The mucus [on the outside of slugs and snails], which is the basis for their locomotion, is very high in water content," . . . [Hollingsworth] observes, and it permits water-soluble caffeine easy entry. Once inside the critters, the new Hawaiian studies show, the neurotoxic caffeine destabilizes the mollusks' heart rate. . . .

According to the 2001 opus *The World of Caffeine* by Bennett A. Weinberg and Bonnie K. Bealer, . . . exploitation of this natural poison comes at a price because "the very drug that helps [plants] destroy their enemies ultimately kills them as well." With coffee, for instance, as branches, leaves, and berries fall to the ground, caffeine leaches out of this litter, eventually enriching soil caffeine concentrations to a point where they become toxic to the parent plant. This is one reason that the productivity of coffee plantations tends to wane with time.

The Best Coffee Substitute Ever

Chicory may look like scraggly lettuce, but it's an amazing plant. Not only are the leaves nutritious, but the brewed roasted roots taste like coffee, with a robust, satisfying flavor and rich, creamy mouth feel. Research shows that chicory nourishes the liver and increases the flow of bile, thus improving fat digestion. Chicory also purifies the blood, is high in antioxidants, and has anti-inflammatory effects. It even improves insulin uptake in the cells, which balances and regulates blood sugar levels.

Brew as you would regular coffee, using an ordinary coffee maker or a French press.

triggers the brain to release a chemical that induces brain stem cells to transform into new nerve cells. If this data is true, it may explain reports that moderate coffee drinkers have lower rates of Alzheimer's and Parkinson's Disease than abstainers (or a delay in the onset of those conditions). This could also account for reports that coffee promotes anti-aging effects on the brain.

Another widely publicized benefit of coffee pertains to its bioflavonoid content. Among other functions, bioflavonoids help strengthen blood vessel walls, scavenge free radicals, protect collagen, prevent inflammation, and reduce stress and improve mood by helping the body produce vital neurotransmitters. As bioflavonoids are abundant in fruits (especially citrus), and many vegetables—including broccoli, garlic and spinach—it seems foolish to drink coffee for its bioflavonoids when other, better options are available. Also, pro-coffee studies don't mention what form of coffee is being researched. Bioflavonoids degrade when heated.

Knowing that over half of the scientific reports we read are distorted or fabricated (see Chapter 1), is there even a particle of truth to any of these glowing claims? Under what circumstances might these glowing reports be true? And how do we assess coffee's apparent advantages against the damage? Part of the answer, at least, may depend on the health status of the coffee drinker, as well as on how the coffee bean is grown and harvested: its freshness.

Coffee's freshness is more important than you might think. The beneficial oils in the coffee bean are so fragile, they start to degrade as soon as the bean has been roasted. They further decompose after the beans are ground. The most discerning coffee aficionados buy the beans raw (which are green), roast the beans in a special roaster, grind the beans after removing them from the roaster, and then immediately make the beverage. *This is the only way to ensure that the coffee is fresh.* If the ground coffee is even one day old, the delicate oils have already begun

to turn rancid. This degradation of the volatile oils is not perceived by the average consumer as rancidity, however; people merely assume that coffee is inherently bitter. But truly fresh coffee is not bitter—it's incredibly mild, and possesses many complex and delicious flavors. In fact, it's easy to drink fresh coffee without adding anything else to it, not even sugar. Commercially roasted and ground coffee, which has been sitting on the store shelf for many weeks if not months, is what most people think of as coffee. So what they drink, and perceive of as "normal" coffee, is stale! From a health standpoint, this staleness indicates that the beneficial oils have already deteriorated into toxic compounds.

Until six years ago, in my entire life I drank probably fewer than one hundred cups of coffee. I was never drawn to it—but after buying my own roaster and grinder and drinking the beverage fresh, I was hooked. Beans that had been roasted and ground 24 hours ago were not as good as beans that were roasted and ground within the last 30 minutes. The fresh brew tasted better, was smoother, and even seemed to have uplifting energy. Some say that freshly roasted and ground coffee lasts for two weeks before it begins to degrade, but that was not my experience.

If you do decide to drink coffee, buy organically grown beans, as most coffee is heavily sprayed with toxic pesticides. Make sure that you drink it within one day of roasting and grinding the beans. If you don't want to roast and grind beans every day, store the excess in the freezer, or vacuum seal it to maintain freshness. (The unroasted, raw green beans last for up to two years in the freezer.) Some coffee connoisseurs prefer brewing in a French press without a filter, as even an unbleached filter is said to absorb the antioxidants. And don't add sugar to the brew; this will cause insulin spikes. Finally, if you own a water electrolysis unit, make the coffee with alkaline water set to the highest possible (most alkaline) pH setting. This will offset the negative effects of the acids (remember, coffee has a pH of about 5.0).

Before you decide to drink coffee (or more of it), please note that my fresh coffee story doesn't have a happy ending. It took four years to reverse some of the damage I inflicted on my adrenals, and even then, my recovery was only partial. *Any benefits of coffee pertain only to those who have a strong immune function, a balanced nervous system, and strong adrenals.* The benefits may also be non-existent, depending on how the coffee has been processed. If you suffer from erratic blood sugar levels, adrenal fatigue, or a severe health problem such as Lyme or cancer, drinking even freshly roasted coffee is unwise. You can buy some good-tasting coffee substitutes containing roasted chicory in health food stores and even supermarkets.

Soda

This sweetened, carbonated beverage, also known as a soft drink or soda pop, comes in a huge variety of sizes, colors, flavors and fizz. Soda comprises more than a quarter of all drinks consumed in the United States. The rate of consumption averages around 216 quarts (or 204 liters) per year per person.³² “Kids are heavy consumers of soft drinks, according to the US Department of Agriculture, and they are guzzling soda pop at unprecedented rates,” writes reporter Sally Squires. “Fifty-six percent of 8-year-olds down soft drinks daily, and a third of teenage boys drink at least 3 cans of soda pop per day.”³³

There isn’t one positive thing to say about this synthetic concoction. Many people drink it, so its effects on the body are worth describing in detail.

Soda pop, points out Squires, “provides more added sugar in a typical 2-year-old toddler’s diet than cookies, candies and ice cream combined.”³⁴ That’s a lot of sugar! Two years old is also a young age at which to start the soda pop habit. “Not only are soft drinks widely available everywhere,” Squires adds. “They’re now sold in 60% of all public and private middle schools and high schools nationwide, according to the National Soft Drink Association. A few schools are even giving away soft drinks to students who buy school lunches.”³⁵

Soft drinks contain carbonated water, phosphoric acid, sugar (or a synthetic sweetener sugar substitute), flavorings, preservatives, and often caffeine. Here is a brief summary of the damage caused by these ingredients:

- ◆ *Sugar.* If a caloric sweetener is used, it’s usually either sucrose (table sugar) or high fructose corn syrup. Many people have allergies or sensitivities to corn. In addition, high amounts of fructose stress the liver and cause weight gain (discussed in detail shortly).

Sugar provides a fertile breeding ground for bacteria, which cover the teeth with a film called *plaque*. Plaque disintegrates the tooth enamel, causing holes or cavities that can eat into the nerve-rich soft tissue (dentin). Plaque also lodges between the gums and the teeth, creating pockets of infected material that cause the gums to recede and leave the root of the tooth exposed.

There is abundant scientific data proving that sugar causes obesity. Children who drink soda are almost twice as likely to become obese than those who do not. *Obese* does not merely indicate overweight. An obese person is more than 20% over his or her maximum healthy body weight. Obesity contributes to diabetes and heart attacks. Squires reports that Harvard University researchers “found that schoolchildren who

drank soft drinks consumed almost 200 more calories per day than their counterparts who didn’t down soft drinks. That finding helps support the notion that we don’t compensate well for calories in liquid form.”³⁶

Sugar depletes vitamins and minerals because the body requires abnormally high levels of nutrients to process the sugar. Sugar also acidifies the system. This forces the kidneys to work harder to eliminate the disease-causing wastes.

- ◆ *Phosphoric acid.* The phosphorous in phosphoric acid binds to calcium, thus preventing the body from absorbing it. This calcium deficit manifests in all bone tissue in the body, including the teeth. If you immerse a tooth in cola, you can see it dissolve. The phosphoric acid “begins to dissolve tooth enamel in only 20 minutes,” notes the Ohio Dental Association.³⁷ When bones are depleted of calcium, they become more porous and brittle. Calcium loss from bone affects five times more girls than it does boys, leading to more fractures and breaks. As adults, these girls are much more likely to develop osteoporosis.

Phosphoric acid also causes the aluminum in cans to leach into the liquid. When you drink soda, along with everything that’s supposed to be in the can, you’re guzzling a toxic heavy metal.

Finally, phosphoric acid unbalances the body’s pH. As the name implies, it makes the body much more acidic. As with sugar, this forces the kidneys to work harder.

- ◆ *Caffeine.* Not all cola drinks contain caffeine, but many do. A 12-ounce can of typical cola can contain from 35 to 38 mg of caffeine. This is roughly 28% of the amount of caffeine contained in an 8-ounce cup of coffee. “Few know that *diet colas*—usually chosen by those who are trying to dodge calories and/or sugar—*often pack a lot more caffeine*,” points out Squires. [original emphasis]³⁸ Just one example she gives is 42 mg of caffeine for a 12-ounce can of Diet Coke®—which is seven times more than that found in the same amount of Coca-Cola Classic®.

The effects of caffeine were covered in the previous pages devoted to coffee. Even though some of the caffeine found in many sodas is naturally derived from kola nuts, it’s still addictive. “Why is this drug, which is known to create physical dependence, added?” Squires asks. “When you are dependent on a drug, you are really upsetting the normal balances of neurochemistry in the brain. The fact that kids have withdrawal signs and symptoms when the caffeine is stopped is a good indication that something has been profoundly disturbed in the brain.”³⁹

The Dangers of Fluoride

One of the biggest scams perpetrated on the public is the notion that fluoride is safe, and that it prevents cavities.

Unlike the natural gas fluorine—or the edible salt calcium-fluoro-phosphate that's derived from foods, can't be dissolved in water and is assimilable by the human body—fluoride is not a natural element. A byproduct of the aluminum and fertilizer industries and a poison, fluoride is more toxic than lead and only slightly less toxic than arsenic. In 1931, after the US Public Health Service discovered that fluoride in water damaged teeth, it called for the removal of fluoride from the air and from water in areas that had been contaminated by industrial pollution. Court actions for personal injury were filed against the polluters, who were also forbidden to dump their waste into the public waterways.

How was this common knowledge suppressed? In 1939, a biochemist on the staff of the Mellon Institute—the same Mellon family that owned Alcoa Aluminum Company—devised a clever plan to unload the toxic waste onto the public at no cost to industry. He claimed that even though some fluoride was bad for the teeth, a tiny amount was beneficial. So he fabricated a study claiming that fluoridated water would prevent dental cavities. Therefore, instead of having to pay to dump all that poisonous waste, the polluting companies were paid for it.

Even so, in September 1943, the *Journal of the American Medical Association* reported that fluoride inhibits key enzyme reactions in a cell by disrupting the shape of the proteins that comprise the enzymes. And in October 1944, the same journal stated that drinking water containing as little as 1.2 ppm (parts per million) of fluoride causes serious conditions: abnormal hardening and densification of bones, degeneration of joints and spinal discs, and goiter (the pathological enlargement of the thyroid gland). Honest data began to be buried when in 1944, an attorney on the payroll of the Aluminum Company of America was appointed as head of the Federal Security Administration. The US Public Health Service, which at that time was a division of the Federal Security Administration, suddenly began promoting fluoridation.

Fluoridation is the practice of adding silicofluorides to water at 1 ppm. Even this tiny dose has devastating effects. Evidence of harm has been proven on every continent, except when results have been deliberately withheld or misinterpreted. Additional research shows that fluoride causes skin rashes, convulsions, blood vessel calcification, gastrointestinal disorders, arthritis, aching bones, bloody vomit, immune malfunction, genetic and birth defects, cell death, infertility, and increases in deaths from liver, bone, and other cancers. Fluoride inactivates 62 enzymes. Moreover, in most cases fluoride *mottles* and *destroys* teeth rather than preserves them. Fluoride does cause the enamel to become harder, but it also erodes it by interfering with calcium absorption, causing a condition

known as *fluorosis*. This can affect the entire skeleton, which is why at least fourteen Nobel Prize winners in chemistry and medicine, and no fewer than 1,500 scientists at the US Environmental Protection Agency, have opposed the fluoridation of our drinking water.

The legal classifications of fluoride are revealing.

- ◆ According to the EPA, sodium fluoride is the second most dangerous class of pesticide. The FDA has never approved fluoride supplementation as safe or effective.
- ◆ In the United Kingdom, silicofluorides are a class 2 poison under the Poisons Act, and are illegal.
- ◆ The European Union has banned fluoridation due to the health risks. Ninety-eight percent of Western Europe is now fluoride-free, with no rise in tooth decay.
- ◆ Most developed nations do not fluoridate the majority of their water supply. But in the US, 67.1% of the population receives fluoridated water.

Fluoride affects mental function due to its narcotic effects on some regions of the brain. World War II Allied soldiers who liberated the concentration camps found stockpiles of fluoride near the water supplies. In 1954, chemist Charles E. Perkins wrote that a German chemist once prominent in the Nazi movement informed him that the Nazis had added fluoride to the prisoners' drinking water to make them more docile and easy to manipulate. Perkins wrote that after nearly 20 years researching the "chemistry, biochemistry, physiology and pathology" of fluoride, he concluded that anyone drinking fluoridated water "for a period of one year or more will never again be the same person mentally or physically."⁴⁰ Over 300 scientific studies—including one from Harvard School of Public Health—show that fluoride causes brain damage, dementia, reduced cognitive function, and lowered IQ. These studies are listed at fluoridealert.org/issues/health/brain. Note that one form of fluoride, fluoxetine hydrochloride, is a main ingredient in Prozac®.

By law, all toothpaste containing fluoride must warn the consumer to seek medical help or contact a poison control center immediately if more toothpaste than is "normally" used for brushing is accidentally swallowed. A director of research and development for oral and personal care products was once quoted as saying, "When I receive the fluoride here, it has a skull-and-[cross]bones on it"⁴¹—the graphic symbol for "poison." At one time, sodium fluoride was used to kill rats; hence, its classification by the EPA as a pesticide.

Tooth decay is not due to a rat poison deficiency, but a scarcity of nutrients—calcium, phosphorus, zinc, Vitamin D3. Yet fluoride continues to be put into our foods, beverages, medicines, dental products, and water. Are fluoridation proponents now too brain damaged to understand (or care) what has happened to them?

- ◆ *Artificial Sweeteners.* Not all cola drinks contain artificial sweeteners, but “diet” sodas do. Many people who consume these drinks believe that because they contain non-caloric artificial sweeteners, they are healthier than sugary sodas. This isn’t true. The most popular synthetic sweeteners are aspartame and sucralose, and sometimes saccharin. Saccharin is a proven carcinogen, as are aspartame and sucralose, which also inflict extensive, sometimes permanent damage to the liver, muscles, nervous system, and brain. The politics and some negative health effects of aspartame were discussed in Chapter 1. More details on the health hazards of aspartame and sucralose will be discussed later in this **Food** section.

One more thing. The sugar (or synthetic sweetening chemicals), flavorings, and phosphoric acid require massive amounts of water to flush them out of the body. Soda pop users are often dehydrated, as they don’t drink enough water. If you’re rifing, you need lots of water to dilute the poisons from devitalized pathogens. Why drink soda at all?

Black and Green Tea

The popularity of tea as a beverage dates back thousands of years to the Orient. According to legend, a Chinese emperor (who was also a renowned herbalist) sat beneath a tree while his servant boiled drinking water. Some leaves from the tree blew into the pot, the man tried the infusion, and the drink we call “tea” was born. This drink is so prized, that leaves have been found in ancient tombs.

Technically, tea refers to one specific plant called *Camellia sinensis*. The green leaves are steamed to prevent them from degrading. Black tea is simply green tea whose leaves have been left to oxidize (break down) and ferment. The fermentation process used on the leaves destroys the delicate bioflavonoids and other beneficial components to such an extent that for some people, black tea can cause more damage to the kidneys than even coffee. Like coffee and soda, black tea dehydrates the system.

In both holistic circles and the mainstream press, green tea is touted for its high bioflavonoid and antioxidant content. Independently, both substances can help prevent cancer and other diseases; but in green tea, especially if it’s drunk on a long-term basis, there may be problems. Tea leaves contain caffeine and other volatile oils. Caffeine causes mineral depletion because it acts as a diuretic, forcing too much liquid at once through the kidneys. The second disadvantage is the natural tendency of the *Camellia sinensis* plant to accumulate the toxic metal fluoride. If the plant is growing in an area with heavy air and soil pollution, fluoride will be present in even

larger amounts than usual. Fluoride is so well known for impairing the thyroid gland’s ability to secrete thyroid hormone that it was once routinely administered in cases of hyperthyroidism (abnormal hyperactivity of the thyroid)! A cup of green tea contains an average of 7.8 mg of fluoride—much higher than the amounts once given as medication to treat hyperthyroidism. (See Insert, “The Dangers of Fluoride.”)

Green tea may still have a place in the diet, however. Fluoride levels in the tea were undoubtedly lower before modern pollution. Also, green tea may not have been as dangerous long ago because in the Orient it was sipped rather than gulped. Finally, the traditional Oriental diet consists of fish and seaweed, whose high iodine levels help protect the thyroid. Therefore, if you drink green tea, make sure it’s organic, don’t overdo the amount, and increase your iodine intake.

High-Sugar Vegetable and Fruit Juices

Fruits have many beneficial properties. Black cherries are anti-inflammatory, and are successfully used to help eliminate gout. Blueberries and other berries are high in antioxidants. However, fruit’s high fructose content (even though it’s naturally occurring) stimulates the reproduction of sugar-hungry pathogens—thus increasing toxic waste levels in the body. Thus, for people with infections, a fruit’s benefits may be eclipsed by fructose.

If fruit is questionable for a sick person’s diet, imagine the effects of fruit *juice*. It takes much more fruit to make a single glass of juice than what one could possibly ingest in one sitting, because juice doesn’t contain fiber. Without fiber in the stomach to act as a buffer for all that extra sugar, the fructose rapidly enters the bloodstream and causes insulin spikes. (Later I discuss the damage to the liver caused by fructose.) Fruit’s high sugar content explains why people with severe infections often get worse when they drink fruit juice.

Carrot, which is a root vegetable, contains as much sugar as fruit. Pathogens appear to thrive on carrot sugar the same way they thrive on the fructose in an apple or melon. However, many people have found that the antioxidants and some other, unknown compounds in carrots have made carrot juice indispensable for eliminating cancer. The most successful cancer protocols require very high amounts of carrot juice. Three pounds of juiced carrots per day may not yield results, but five pounds will.

Greens contain high amounts of nutrients without the destructive sugars. By using mostly greens for your juice, you’ll still obtain valuable vitamins, minerals and enzymes without encouraging the proliferation of pathogens.

The Healing Properties of Green Grasses

To many people, “green grass” means the rolling lawns of their favorite golf course or the stuff that causes allergies, wheezing and runny noses in the springtime. However, the right kinds of grass can be healing if they’re in juice or powdered juice form. Wheat and barley are usually used. Their grains cause health problems due to their gluten content, but the young green shoots do not—as long as they’re juiced before they’re 11 or 12 days old, before the grass splits into two blades and begins to form a glutinous seed.

The juice from wheatgrass (*Triticum aestivum*) is 70% chlorophyll and has almost the same chemical structure as the hemoglobin in human blood. It contains all the known minerals, and Vitamins A, B-complex, C, E, and K. Wheatgrass is high in protein (17 amino acids) and antioxidants. It builds blood by increasing the oxygen-carrying ability of red blood cells. It improves immune function, removes toxic metals from the tissues, and contains a compound that kills bacteria. And it’s anti-inflammatory. Studies have also shown that wheatgrass binds to carcinogens.

The juice from barley grass (*Hordeum vulgare*) contains abundant chlorophyll, is rich in iron and calcium and ten other minerals, and is high in Vitamins A, B-complex and C. Barley grass also contains every essential amino acid, with 23% high quality digestible protein in each serving. This grass is becoming famous for helping balance blood sugar levels: studies have shown very favorable results for people with diabetes. Barley grass lowers high levels of “bad” cholesterol and raises levels of “good” cholesterol. It improves circulation. It reduces free radical levels due to its antioxidant properties. And it stimulates the growth of friendly intestinal flora and reduces inflammation.

Grasses must be grown and processed correctly. The best wheatgrass is grown outdoors in soil, slowly (including through the winter)—not rapidly indoors in trays under warm lights, which changes its chemical composition, diminishes its nutrients, and often promotes mold growth. However, those who cannot obtain outdoor-grown wheatgrass do benefit from the chlorophyll in tray-grown wheatgrass. If you use powdered rather than fresh grasses, they should not be processed with heat.

Many people believe that any nausea they might feel is the result of detoxification. However, it’s more likely a result of the grass’s sickening sweetness, which is augmented if it has been grown in weeks instead of months. You don’t need to drink much. Most people begin with ½ to 1 teaspoon of powdered grass in 8 ounces of water, gradually increasing the quantity to 2 tablespoons. Alone, grass tastes like—well, grass, but you can add other ingredients to it.

Canned and bottled juices are not nutritionally valuable. Pasteurization (heating) renders juice useless because the high heat kills the enzymes and many important nutrients. Vital enzymes in juice degrade fairly quickly—usually within an hour after the juice is extracted—so the benefits of juicing are lost if you wait. If the juice is fresh squeezed, drink it immediately.

As juicing creates a very concentrated, therapeutic substance, many practitioners agree that one should consume juices only if there is a special need, such as during a serious illness. People who are ill generally suffer from substandard digestion. The advantage to liquid nourishment is its easy absorption by the body.

Green Juices and Green Smoothies

Many holistic practitioners suggest fresh vegetable juice daily during a cleansing or restorative program. Fresh vegetable juice contains valuable enzymes that catalyze all chemical processes in the body, aid digestion, and repair tissue. People who have a difficult time assimilating solid food can help repair their gut, and acquire valuable nutrients at the same time, simply by drinking juice.

Carrot is considered a staple for vegetable juices, but as previously stated, its sugar content may be too high for people who don’t have cancer but suffer from other, severe infections. Cucumber, celery, and parsley are a good base for a vegetable drink.

The grasses of wheat and barley have tremendous healing capabilities (see Sidebar, “The Healing Properties of Green Grasses”). However, juiced greens are so potent that they can cause the liver to detoxify too rapidly and dump its stored toxins into the bloodstream, which causes nausea and even vomiting. For this reason, beet—which is a potent liver and gallbladder cleanser—should also be used in very small amounts. If you cannot obtain fresh juice, powdered young grasses mixed in water are an acceptable substitute. Be aware that not everyone responds well to fasting on juice alone. You can always use juice to supplement a diet of solid food.

If you don’t own a juicer, or have access to a place that sells fresh squeezed vegetable juice, a wonderful substitute is liquid chlorophyll, sold in bottles at the health food store. Chlorophyll can be regarded as the “blood” of a plant. It has an almost identical composition to human blood, with one major difference. Human blood is high in iron, which gives it a red color, and plant chlorophyll is high in magnesium, which gives it a green color. As most people are deficient in magnesium, supplementing the diet with chlorophyll-rich green juice is wise. If you don’t like the taste of chlorophyll, you can find chlorophyll products flavored with mint to make them more palatable.

While vegetable juice is easy to digest and provides the body with valuable nutrients including enzymes, there's another, equally valid way to eat your vegetables raw: by blending them. This produces a fiber-rich drink that Victoria Boutenko, in her book *Green for Life*, calls "green smoothies." Boutenko wrote that fiber binds excess estrogen, escorts debris from the gut, provides food for the friendly intestinal flora, and even possesses anti-cancer properties. In 2014, when health writer Mike Adams (naturalnews.com) reported that his laboratory tests found heavy metals in many foods (both conventional and organic), he also stated that vegetables and fruit fiber binds and escorts the metals from the body. The value of vegetable and fruit fiber cannot be understated.

Celery, peeled cucumber, lettuces, and lemon (including the peel, if it's organic) make an excellent base for any green smoothie. The addition of parsley, avocado, tomato and garlic creates a rich thick soup or sauce, while banana, mango or apple provide a sweeter shake. Green

smoothies give the digestive tract a rest while providing optimum nutrition. For many people, green smoothies may be a better choice than juice without fiber.

Herbal "Teas"

The recent popularity of leaves, roots, berries and bark that impart such wonderful flavors in boiling water has helped wean people off both coffee and tea. The study of herbology requires an entire book, so only a few highlights will be given here.

As mentioned earlier, only the *Camellia sinensis* plant can technically be called "tea." However, the phrase "herbal tea" has become part of everyday word usage. Even some chain restaurants now offer herbal "teas" along with the usual coffee and tea.

People often like these herbs for their effects as well as their flavor. Although some claim that "tea" herbs (such as peppermint, chamomile, hibiscus flowers and

Beware of Vitamin B12 Analogue in Sea Vegetables

An *analogue* is something that's similar, but not identical, to something else. When dealing with chemical compounds, an analogue can be structurally related and even have similar functions, but it cannot replace the original.

Most of us want the real thing, not an analogue. While some analogues may be suitable substitutes, when it comes to vitamins, an analogue can be downright harmful. Take Vitamin B12. A B12 analogue is similar enough to the real vitamin to latch onto the body's receptor sites for B12. However, the analogue doesn't do the job of B12. Ultimately, it will cause Vitamin B12 *starvation* because as long as the receptor sites are being usurped by the phony, the body cannot access the real vitamin.

Doctors have known about this problem for at least three decades. Just two medical journal articles on the topic are: "Vitamin B-12 from algae appears not to be bioavailable."⁴² and "Vitamin B-12 status of long-term adherents of a strict uncooked vegan diet ('living food diet') is compromised."⁴³ Vitamin B12 analogues are contained in most sea vegetables: spirulina, blue-green algae, and dulse. Interestingly, nori appears to be one of the few seaweeds that contains real (not analogue) Vitamin B12 as long as it's eaten raw and not toasted. (It's almost always eaten toasted, however.) Chlorella, a high-chlorophyll microscopic plant related to algae, is rich in enzymes, vitamins, minerals, fatty acids, mucopolysaccharides, nucleic acids (RNA and DNA), and all the amino acids (chlorella is over 50% protein). Unlike other forms of algae, chlorella doesn't appear to contain significant amounts of B12 analogue. (Keep in mind that the biologically compatible form of B12 is the absorbable *methylcobalamin* and not the cheaper *cyanocobalamin*. Cyanocobalamin contains a tiny bit of cyanide, which the body must expend extra energy to remove.)

The daily requirement of B12 for most people is only about 10 micrograms per day (not milligrams, which is one hundred times more). A B12 deficiency can take more than five years to develop, but when it does occur, severe problems arise. Symptoms include fatigue; weakness; cramping, tingling and numbness in the limbs; heart palpitations; breathing difficulties; constipation, diarrhea or loss of appetite; sore tongue; vision loss; and neurological damage including confusion, depression, memory loss, hallucinations, and dizziness. Anemia develops, which is low systemic oxygen levels due to either an abnormally low red blood cell count or not enough oxygen-carrying hemoglobin inside of the red blood cells. It's the insufficient oxygen that produces many of the B12 deficiency symptoms.

While some Vitamin B12 is made by friendly intestinal flora, additional amounts must be obtained from external sources such as food and nutritional supplements. The most efficient delivery system is animal products: muscle meats, eggs, seafood, dairy products, and especially liver. If one's diet is vegetarian, the need for B12 supplementation is mandatory. If seaweed is a regular part of a vegetarian's diet, B12 supplementation may literally save a life.

True B12 in a food may be ineffective if comparable amounts of its analogue are eaten in the same meal. Unfortunately, the two compete and the phony always wins. However, the analogue won't be a problem if you ingest seaweed several hours away from the real thing, either in the form of animal products or a B12 supplement.

Healthy Spice Drink for a Sweet Tooth

- ◆ 12 cinnamon sticks, about 2¾ inches long (do not use powder, or else the drink will be bitter; see note below about cinnamon)
- ◆ ½ heaping teaspoon whole allspice
- ◆ ½ heaping teaspoon whole cloves
- ◆ 1 heaping teaspoon peeled chopped ginger
- ◆ ½ teaspoon hulled cardamom
- ◆ ½ teaspoon whole fenugreek
- ◆ 1½ tablespoons loosely packed shredded Chinese tangerine peel (*Citrus reticulata*), optional
- ◆ ½ teaspoon powdered green stevia leaf, optional
- ◆ 6 quarts water (less if you want a stronger drink)

Directions. Boil water. Add all ingredients except stevia and don't allow water to boil again. Simmer about 45 minutes, or until the tightly curled *cassia* cinnamon bark flattens somewhat or the *verum* cinnamon falls apart. Strain immediately so the drink doesn't become acrid. Refrigerate for up to three days, or keep overnight in a thermos. This drink is good cold or gently reheated. Add stevia powder just before serving.

Collectively, the ingredients balance blood sugar (*cassia*, more so than *verum*), induce sweating, aid digestion, open the sinuses and respiratory tract, dispel excess moisture, warm the body, and improve cognition. They also have antibacterial, antiviral, and antifungal properties.

Important information about cinnamon. If you're planning to drink a lot of this beverage, be aware that there are about a dozen different species of tree known as "cinnamon." True cinnamon, found in Ceylon and known as *Cinnamomum zeylanicum* or *Cinnamomum verum*, is expensive and hard to find. Its bark is soft, layered and very sweet. Its cheaper, readily available cousin, *Cinnamomum cassia*, has hard, more smoothly textured bark, and is a bit less sweet, with a sharpness to its taste. Although all species of cinnamon bark have similar effects, the true cinnamons contain less coumarin than *cassia*. *Coumarins* are naturally occurring plant compounds that have strong anticoagulant properties. This is important to know because normally, when the body is injured, blood coagulates at the injured site (which is what you want). But if you ingest too much coumarin over a long period of time—which will happen if you drink this beverage often and make it with *cassia*—the blood will no longer coagulate easily when you need it to. On the other hand, *cassia*, more successfully than *verum*, appears to inhibit the progression of Alzheimer's. Therefore, it's worth experimenting with both types.

ginger) have no restorative effects and are merely appealing beverages, herbalists (and my personal experience) indicate otherwise. Even modest "tea portions" of various plants offer benefits. For example, peppermint stimulates better digestion and encourages wakefulness. Chamomile calms the nerves and induces sleep. Hibiscus, with its distinctive tangy flavor, contains many compounds—including quercetin (a bioflavonoid), which helps with allergies and circulation. The **Herbs** section later in this chapter addresses what makes an herb medicinal.

Coaxing satisfying and subtle flavors from herbs is an art. For leaves and delicate plant parts, heat the water to just under a boil and then steep the leaves. Don't let the leaves sit in the water for too long; otherwise, they'll become bitter. Dried berries, bark, and especially thick rinds, which contain numerous heavy layers of tough plant cellulose, require a more rigorous approach of boiling for 20 to 40 minutes, and occasionally longer.

Ginger root has a well-deserved reputation for being the most widely used herb on the planet. A favorite with cooks, ginger also relieves colds, allergies, arthritis and asthma, and helps protect the digestive tract and liver from toxins and parasites. It also stimulates digestion and alleviates nausea, making it popular during pregnancy. See Insert of a drink I invented, "Healthy Spice Drink for a Sweet Tooth." It uses ginger as a main ingredient and doesn't contain sugar or fruit. The number of non-caffeinated beverages is limited only by your imagination.

FOOD

One Size Does Not Fit All

Did you ever go shopping for a "one-size-fits-all" bathrobe? If you're 5 feet tall (my height), and if you have a friend who's 6 feet tall (like my business partner), and both of you try to fit into the bathrobe, you'll quickly learn that this claim does not coincide with reality. Yet the public is constantly told that this one-size-fits-all mentality applies to everything, including diet.

No one can dispute that good health depends on eating properly. The problem is, even "experts"—in holistic as well as mainstream medical arenas—disagree as to what constitutes the optimum diet. There are many types: macrobiotic, vegetarian, vegan, raw food, Ayurvedic, high complex carbohydrate, low fat; the list is endless. Have you ever asked yourself why popular diets contradict each other so much? "How can they all be right?" you wonder. "Why does my friend lose weight when she eats certain foods, and I gain weight when I

eat those same things?” Or, “Why does a juice fast make my husband feel great, while I just feel tired?”

Many factors determine the best diet for an individual: genetics, race, cultural practices, body type, season, age, health status, environmental toxin exposure, and belief systems. Of the many factors to consider in planning an optimal diet, a few variations are discussed below.

Geographical Ancestry

In *Nourishing Wisdom: A Mind-Body Approach to Nutrition and Well-Being*, nutritional psychologist Marc David notes that the diets of the Earth’s peoples who “live near mountains, oceans, rivers, deserts, tundra, tropics, forests, and flatlands” are as varied as the terrain that grows their food. “Is it sensible for any one . . . to tell another about the ‘true’ way to eat? Can a tribesman from West Africa whose staple food is cassava root tell an Eskimo he is wrong because his staple food is fish? Or can the Japanese tell the Mexicans of the absurdity of eating dairy, corn, hot peppers, and food fried in lard, staple products completely unknown to native Japan?”⁴⁴

“Following a fad diet or a computer-generated diet will only have limited value,” writes nutritionist Judith DeCava in her whimsically titled article, “Food Fights.” “A ‘one-size-fits-all’ approach to diet and all other universal dietary recommendations overlook the tremendous amount of biochemical and physiological diversity among individuals. . . . While one’s specific ancestral heritage may be of critical importance in ascertaining ideal foods to consume, identifying the diet that will best support one’s health is much more complicated . . . There are simply too many factors that influence nutritional needs. . . . No wonder the diet ‘experts’ are essentially unable to achieve consistent, predictable results with their followers.”⁴⁵

Gut Flora

The assimilation and metabolization of foods is hugely dependent on the flora living in the gut—also known as the *microbiome* population—which is inherited from the mother. The gut houses between 300 and 500 species, whose numbers are twice the amount of cells in that same human body. These flora should be respected: They regulate our cravings, motivation, moods, and even our outlook on life. They also help regulate weight. When a greater variety of flora from skinny mice were implanted in mice who normally become obese, the hefty rodents slimmed down. The opposite held true: slender mice became fat when their microbiome population was altered, due to implants from their fatter counterparts. Humans react the same way. Just one article of many is “Impact of the Gut Microbiota on the Development of Obesity: Current Concepts,”⁴⁶ written in 2012.

Biochemistry and Metabolism

In the last couple of decades, diet books have emerged that are based on some form of biochemical assessment. De Cava points out some of these factors: the individual’s metabolic rate, acid-alkaline balance (it’s more complicated than you might think), and sympathetic or parasympathetic nervous system dominance. When all the unique biochemical aspects of the body are considered, she concludes, people represent at least five thousand variations in biochemistry.

Despite the complexity of human biochemistry, most popular literature is based on simplistic science—if indeed it could be called “science” at all. One book suggests eating food according to endocrine type. Another bases food choices on blood type. Yet a third system, prevalent in books and on the Internet, arranges foods according to their presumably acidifying or alkalizing effects on the body, and teaches that inherently acid or alkaline foods affect the body’s pH correspondingly once they’re ingested. Enthusiastic devotees claim that most people are too “acidic,” and eating so-called alkalizing foods will correct the acidity. The problem is, one’s endocrine or blood type plays just one role of many in ideal diet; and most of the information on food and systemic pH is incorrect. Physician Harold Kristal and co-author James Haig explain variations in metabolism that cause people to be affected in opposite ways when eating the same foods. “Major Tenets of Metabolic Typing,” from their book, is so important that it’s a Sidebar on the next page.

Conventional nutritional wisdom holds that any particular food will have the *same* pH effect in anyone who eats it. Thus it is commonly said that protein foods (especially animal proteins) are generally acid forming, and that fruits and vegetables are generally alkaline forming. But, in the world of Metabolic Typing—where *blood* is being used as the primary pH marker—this would only be true of the two Autonomic types [signifying whether the sympathetic or parasympathetic nervous system is dominant for energy control]. For the two Oxidative types [signifying how rapidly food is converted into energy], the opposite would apply: most animal proteins would be alkaline forming, and most fruits and vegetables would be acid forming. Almost all other nutritionists who work with pHs use urine and/or saliva—not blood—as their primary marker. This is simply for ease of access. . . . [But] urine and saliva [are] much more changeable and, therefore, less reliable as metabolic markers than blood pH. . . .⁴⁷

Major Tenets of Metabolic Typing

- ◆ We are all biochemically unique, with different constitutional and genetically inherited nutrient requirements.
- ◆ People are predisposed to greater or lesser dominance in either the Oxidative system (the conversion of nutrients into energy) or the Autonomic system (the distribution of that energy via the autonomic [involuntary] nervous system).
- ◆ The Oxidative system consists of Fast and Slow Oxidizers (determined by the speed at which they convert nutrients into energy).
- ◆ The Autonomic system consists of Sympathetic and Parasympathetic types (determined by which of the two branches of the autonomic nervous system is more active).
- ◆ There are foods that are bad for everyone (sugar, white flour products, partially hydrogenated oil, deep-fried foods, chemical additives, etc.).
- ◆ There are good foods that are bad for you, as well as good foods that are good for you, depending on your Metabolic Type.
- ◆ Any given nutrient or food can have virtually opposite biochemical effects in individuals of different Metabolic Types.
- ◆ Foods and nutrients that acidify the two Oxidative types (Fast and Slow Oxidizers) alkalize the two Autonomic types (Sympathetics and Parasympathetics); foods and nutrients that alkalize the Oxidative types, acidify the Autonomic types.
- ◆ An ideal venous blood pH of 7.46 reflects the biochemical balance and metabolic efficiency of a balanced metabolism.

 A Guide to Your Metabolic Type*, 2002

Holistic proponents can be as dogmatic about their preferences as allopathic physicians can be about theirs. For example, the late Robert Atkins promoted a high-protein, relatively high fat and low carbohydrate diet. Dean Ornish promotes a high-carbohydrate, low-fat and low-protein diet. During a television debate between the two doctors, the reason for their preferences was revealed. DeCava reports that after they presented clinical evidence and scientific studies,

Dr. Atkins explained how *his* health improved when he began to follow the diet he now advises for everyone. Dr. Ornish then told how *his* health improved when he changed his diet to the one he now urges people to follow. The same is true for most all diet promoters—whether popular authors or clinicians in private practice—the diet that works for him/her is the one thought to be ideal for all.⁴⁸

It's easy to mistake suggestions for dogma. The way in which a diet is implemented by the public can be quite different from the intentions of the original diet. Or, the reasons for which a diet was developed may not apply to the current user. This appears to have occurred with *macrobiotics*, an approach with purported ties to Japanese Zen Buddhism but which was developed and popularized in the 1950s. The basic tenets of macrobiotics are to eat, in moderation, locally grown food that's in season, with minimal animal protein. Most people, even some high-profile macrobiotics advocates, adhere to a one-size-fits-all diet consisting of rice, vegetables, some seaweed and pickled condiments, and a little bit of fish. This approach has many flaws. What normally might constitute a lovely meal is eaten every day, which for some people can cause nutritional deficiencies and lead to illness. The “fresh, locally grown food” rule can vary widely, depending on one's location. The Inuit (Eskimos) who eat seal meat and blubber (fat from sea mammals—in fact, comprising 80% of their diet) are practicing macrobiotics principles, as are residents of Panama who munch on bananas, coconuts and tamarillos picked ripe almost year round.

Traditional Chinese Medicine (TCM) has a distinctly individual approach to diet. A revealing article in the *Journal of Chinese Medicine*, called “Chinese Nutritional Therapy: A Simple Framework For Prescribing Dietary Recommendations,” asks simple questions. The author appeals to common sense rather than fad.

So what is a healthy diet? From the perspective of Chinese dietary therapy there is no simple answer to this important question. Or rather the answer lies in two counter-questions: “A healthy diet for who” and “A healthy diet when?”⁴⁹

No wonder the average reader has such a hard time with well-meaning diet books!

People's physiological differences undoubtedly form the basis of emotionally-laden opinions on what is good or not good to eat. For example, some people cannot handle moderate amounts of even complex carbohydrates. Too many carbs make them feel mentally unfocused, tired and sick, and cause weight gain. They find red meat perfect

for building their strength. Their counterparts, who cannot digest red meat (or cannot emotionally tolerate the idea of eating it) thrive more on grains and vegetables. I have noticed that some very strict vegetarians and vegans sharply criticize others for eating meat, with a level of emotional charge that seems excessive. Could it be that their diet is causing them to suffer nutritional deficiencies—and corresponding emotional angst?

That said, there are some “foods” that aren’t good for anyone: fake foods. Popular diets that recommend eliminating junk, chemicals, and refined carbohydrates inevitably help most people to some extent. This is why so many diet books on the market that advocate real food instead of junk seem to hold the key to your health (until you find that they don’t).

Each individual has a unique biochemistry, needs, and preferences that cannot be addressed by a simplistic one-size-fits-all system. And sometimes, despite our favorite theories, opinions and even preferences, we need to change what we are eating if we want to feel better.

Current Needs and Health Conditions

What helps you during one period of your life may not work for you during another. “Unlike the horse that must have grain or the lion that must have meat, humans can and do switch metabolic needs, often in midstream as they are healing and reaching a new plateau of wellness,” writes DeCava. “Healing bodies have very different requirements from healed bodies.”⁵⁰ Just as with Rife Therapy, when you use frequencies for *Candida* one day and *Staph* the next—and on some days you don’t do sessions at all—you may find it wise to similarly experiment with your food.

What your ancestors ate can play a major role in what you are evolutionarily designed to eat. However, this guideline can—and should—be modified if your lifestyle is radically different from that of your forebears. For instance, a century ago the people who were farmers needed high-calorie diets high in meat, fat and starch to sustain them for heavy manual labor. Today, more people sit at desk jobs than work in the fields. Such a diet would not only be unsuitable, but would in fact be harmful. Our needs change according to circumstance and location.

Buildup, Breakdown or Maintenance

One interesting dietary paradigm describes the way in which a food affects the system. It either builds up the body, helps the system cleanse and detoxify, or maintains the body. While these effects can vary because people differ in how they metabolize and assimilate, a food will still tend to exhibit one (and sometimes two) of these three functions.

Problems arise if a food’s benefits are not compatible with what your body needs at the moment. This frequently occurs when people eat certain foods to eliminate wastes from their system when they are ill, but continue the same diet when they are well. For instance, as David writes:

Therapeutic diets often facilitate dramatic healing . . . [but] this does not mean they will continue to work on an everyday basis once the body is healed. Often a diet provides therapeutic benefits for a specific period of time and loses its effectiveness when the natural limits of its healing powers are reached. We have seen an example of this in cleansing diets that have positive benefits yet cause negative reactions once the body moves in a building phase.⁵¹

In her wonderfully written and researched book *Food and Healing*, Annemarie Colbin explores this topic in depth. She also discusses the biochemistry of foods, how and why different nutritional systems developed, and which diets work best according to the environment and unique stresses under which the person is living. Although this book was written in 1986, it’s as relevant today as when it was first written.

Nutrient Balance

Another aspect of a food’s suitability is its proportion of proteins, carbohydrates and fats, or its contribution to the total protein, carbohydrate and fat content of the entire meal. The nutrient content of a food (vitamins, minerals, essential fatty acids, enzymes, etc.) also contributes to one’s overall feeling of wellness. People require different amounts and types of nutrients, depending on their metabolism, level of physical exercise, mental exertion, climate in which they live, and state of wellness or illness.

Fads, Trends, and Bald-Faced Lies

Fad is defined by Webster as “an exaggeratedly fussy attitude, especially about eating or not eating certain kinds of food.” My definition of a “fad” is:

- ◆ You keep eating a certain way, even though you look and feel worse.
- ◆ You keep eating a certain way because it is advertised and talked about, even though you look and feel worse.
- ◆ You know all of the “scientific reasons” for eating this way, even though you look and feel worse.

Timing of Eating

Some people function optimally eating a good hearty breakfast in the morning. It helps them wake up, focus, work and relate; and if they don't eat they're grouchy. Others feel better eating lightly or not at all when they awaken; a morning meal makes them feel heavy, lethargic and unable to focus.

That said, the maxim "eat a good breakfast every morning" may still be true. The lack of hunger on awakening could indicate that the metabolic thermostat is not working properly. Many people make the mistake of shocking their body into waking up by drinking coffee. Coffee does diminish hunger, but it accomplishes this by disrupting the body's blood sugar regulation. It would be more productive to eat some animal protein in the morning to reset your metabolism.

Some people face problems if they end their evening meal later than 7:00 p.m. By then (partly because the sun has set, or will soon set), the body is preparing for sleep rather than digestion. Going to bed on a full stomach will almost certainly cause indigestion. Indigestion leads to disturbed sleep and equally disturbing, chaotic dreams. Eating a large, late evening meal is also one of the chief causes of weight gain, especially if there is no exercise afterward to burn the calories eaten. And eating a large meal just before bedtime may curb your appetite for the next morning—which further interferes with the hunger cycle. This explains the wisdom of eating meals at about the same time each day.

You don't, however, want to go to bed hungry; that may keep you awake. See **Sleep and Rest** at the end of this chapter for information on natural substances that help induce sleep.

Atmosphere

The setting in which we eat is an often overlooked, but important, factor in how well we digest, assimilate, and enjoy our meals. In fact, setting is so important that an entire art of interior design, decoration and service is taught by the restaurant industry. Atmosphere is more than the taste, smell, and texture of the food. We need to factor in elements of sight and sound in the environment.

A spacious room with visually pleasing lines helps one focus on digestion, whereas a cluttered room is not restful to the eyes and detracts from digestion. Similarly, music that is soft, melodic and not too fast is soothing to the nervous system, whereas music that is loud, raucous and has a heavy bass beat is stressful.

High-end restaurants emphasize low lighting, uncluttered décor that's easy on the eyes, muted or soft colors, gentle music played at a low volume, and table linens that suggest luxury. All these comforts make diners want to take their time when they eat. Lavish restaurants can afford such features, because the food is pricey. But in a fast food eatery, where food is cheap on many levels (as well as not very nutritious), the goal is to serve as many customers as possible. To induce people to eat quickly, the lighting is bright and harsh, the prominent décor colors are orange and red, and the music has a strong beat and is played at a loud volume. Thus, the establishment compensates in quantity what it cannot deliver in quality. Which atmosphere do you prefer?

Attitude

When I was a child, my mother always used to yell at me not to guzzle my food, but to chew it thoroughly. Now that I am an adult (and a researcher), I understand why. Even though digestive enzymes are secreted by the stomach, pancreas and liver, to repeat an old adage, digestion really does begin in the mouth. The salivary glands secrete an enzyme to digest starch.

The major, initial work of digestion, however, is done by the teeth. The more that the teeth break down food into small particles, the less mechanical motion is required of the stomach later. If you eat when you're in a hurry, or are feeling anxious and angry, the secretion of

digestive enzymes is impaired and as a result, nutrients are not well absorbed. In addition, chronic digestive ailments such as colitis, hiatal hernia, and Crohn's disease may arise. This is why folk wisdom from all over the world advises people to eat only when they are feeling calm and relaxed. The calmness and intention with which you approach your food is so important, it can sometimes even offset the effects of unsuitable food.

There's a saying, "Eat your drink and drink your food." In other words, hold a drink in your mouth long enough for your body to know which biochemical messages (enzymes) need to be activated. And make your solid food watery enough to activate the enzymes as well. Slow eating requires calmness. However, equally important is gratitude towards the life forms that feed us.

Animals and even plants have consciousness. Their self-awareness may not be as sophisticated, complex or recognizable as our own, so it's easy to dismiss other life forms as unaware. However, anyone who lives with a pet, or spends time observing animals in the wild, knows that

other creatures develop social structures, are capable of learning, have distinct preferences, and feel emotions including fear, curiosity, joy, grief, and even love. Two wonderful books that explore this in detail include *The Emotional Lives of Animals* by Marc Bekoff and *Animal Wise* by Virginia Morell.

The reactions of plants are more difficult to detect and generally less known than those of animals, so I'll discuss plants in more detail. The groundbreaking polygraph experiments of lie-detector expert Cleve Backster, which began in 1966, are described in the amazing classic *The Secret Life of Plants*.

The human body's electrical potential—or basic charge—can be measured as it fluctuates under the stimulus of thought and emotion. The standard police usage is to feed “carefully structured” questions to a suspect and watch for those which cause the needle to jump. Veteran examiners, such as Backster, claim they can identify deception from the patterns produced on the graph.⁵²

Backster was teaching a class on lie detection when he watered a tropical *Dracaena* plant that was sitting in his office. In his now-famous landmark demonstration, he spontaneously hooked up his polygraph to a leaf to test the electrical conductivity of the plant. He had assumed that a moister plant would show more conductivity. But the readings did not change. However, when Backster then decided to burn the leaf to which the electrodes were attached, the needle on the machine went wild!

Backster's dragon tree, to his amazement, was giving him a reaction very similar to that of a human being experiencing an emotional stimulus of short duration. Could the plant be displaying emotion? . . .

When Backster left the room and returned with some matches, he found another sudden surge had registered on the chart, evidently caused by his determination to carry out the threat. Reluctantly he set about burning the leaf. . . . [However, when he later] went through the motions of pretending he would burn the leaf, there was no reaction whatsoever. The plant appeared to be able to differentiate between real and pretended intent.

. . . More than 25 different varieties of plants and fruits were tested, including lettuce, onions, oranges, and bananas. The observations [were] each similar to the others. . . . The phenomenon appeared to persist even if the plant leaf [or fruit] was detached from the plant. . . . Even if a leaf was shredded and redistributed between the electrode surfaces there was still a reaction on the chart. The plants reacted not only to threats from human beings, but to unformulated threats, such as the sudden appearance of a dog in the room or of a person who did not wish them well.⁵³

More recent studies show that plants are acoustically sensitive. They will send their roots toward moving water, but not a recording of moving water. They will produce defensive chemicals when their leaves are being eaten by caterpillars, but not when the wind is blowing (which sounds similar to a caterpillar's chewing). Even more remarkable, a plant can recognize when it shares the same container with a sibling—another plant grown from an offshoot of the original plant or cutting—compared to similar unrelated plants. Related plants give each other room to extend roots, rather than competing for soil space.

The ways in which animals and plants perceive, communicate, and express themselves are beyond the scope of this book. My point here is that genuine thanks for our meals is not merely an empty gesture. True gratitude indicates an appreciation and connection to what we have. It does

not need to be expressed under the auspices of religion. Gratitude not only gets our juices flowing (literally), but it transforms us and our surroundings in positive ways.

The knowledge that animals are sentient beings who feel and reflect is often the reason that people become vegetarians. But what about plants? Now that we know plants have feelings too, what is left to eat? The person who can connect to the inherent consciousness of the animals and plants that give their lives to sustain us, sometimes feels deep sorrow. This may partly explain why people can become so argumentative about the “right” way to eat. Perhaps some of us harbor deep feelings of regret that we have to eat at all.

I feel my best when I eat both animals and plants. Giving heartfelt thanks to the plant and animal kingdoms for their sacrifice helps me feel more at peace with my need to consume them.

There is a vast difference between food-faddism and the subject of diets. Diets have become viewed as what a person is *limited* to in eating, whereas they should be viewed as what a person *must* have as nutritional elements.

In Brief

There are many approaches to diet. What we eat is a highly personal matter influenced by biochemical, physiological, psychological, environmental, and cultural factors. People have different needs at different times. Within a wide range of menu choices, some foods are life-sustaining while others are devitalizing. An appropriate food is whatever supports your system and health situation.

A healthy diet involves:

- ◆ The intrinsic quality of the food.
- ◆ The way in which the food is prepared (discussed in detail shortly).
- ◆ How well the food matches the individual's lifestyle, health, ancestry, stress levels, and nutrient needs.
- ◆ The setting in which the food is eaten, which includes the attitude of the eater.

How We Raise Our Food

Eating used to be simple. Our great-grandparents or grandparents would either grow food themselves in their garden, buy from or trade with a neighbor, or—if they lived in a city—buy from the truck that rumbled in a couple of times a week with freshly picked produce from nearby farmers. Even people living on the outskirts of a small city owned chickens so they could eat fresh eggs almost any time they wanted them. Housewives grew herbs on their windowsills, and it was standard practice to bake their own bread and even grind their own flour.

Times today are radically different. More people live in cities than in wide open spaces suitable for farming. With the focus on narrow, specialized skills required by technologically-advanced societies, hardly anyone grows their own food anymore. We are more alienated than ever from the living soil, the source of our sustenance. Foods are no longer vital and nourishing, but highly manipulated commodities that only faintly resemble their animal and plant origins. In fact, food growers are part of the food *industry*. Agriculture has become *agribusiness* and *megaculture*, reflecting the appropriation of family farms by huge conglomerates.

Our great-grandparents and even grandparents would have been baffled by the following definitions, because until the last 50 or 75 years there would not even have been a reason to use the terms. These definitions deal with the “how” of food growing. Directly after, I will discuss the “what”—what specific foods and food groups are commonly available, and how to make the healthiest choices for your individual needs.

Factory Farming or

Confined Animal Feeding Operations (CAFOs)

Food simply used to be called “food.” But with today's modern production methods, “factory farmed” is a specific way of describing how our food reaches us from farm or ranch to table. Factory farmed foods—basic to all conventional supermarkets—are grown and processed in the cheapest and most expedient manner possible. This means that whatever is being grown or raised is treated solely as an item for commerce, rather than as a vital part of the Earth that's intended to nourish us. Standard supermarkets tend not to use the term “factory farmed,” especially in reference to animals, because of how the animals are treated. I will discuss produce first.

The goal of factory farming produce is to create fruits and vegetables that grow quickly, are uniform in size and appearance, can be packed neatly in boxes, and will travel well for shipping—often across thousands of miles, even overseas. To achieve this, only a few varieties of each plant are grown. One of many problems with this *monoculture* system is the lack of resistance to insects and disease.

The vegetables and fruits are grown on huge farms measuring hundreds of thousands of acres, with the latest irrigation equipment, sowing and fertilizing techniques, and harvesting methods. In the United States, according to the US Geological Survey, pesticide use “has remained relatively constant at about 1 billion pounds per year. . . . Agriculture now accounts for 70% to 80% of total pesticide use.”⁵⁴ Millions of tons of chemical fertilizers are applied, and the amounts increase yearly. These chemicals damage the soil, poison our water supply, injure the plants, and harm the health of the people who eat those plants. The soil becomes demineralized, the roots of plants are burned from the phosphates in the fertilizers, and we consume weed killer along with our salad. We don't always see this destruction, so it can be easy to ignore it. The tragedy is, there are wonderful ways to remineralize the soil so that these synthetic chemicals aren't needed. Often, the simple addition of calcium-rich lime is sufficient. (A great source of information is the wonderful farming magazine, *Acres USA*; see References.)

Factory farmed animals are treated just as cavalierly as crops and our precious soil. But because their suffering seems more obvious—their living conditions clearly lead to suffering, serious illness and even death—the plight of these animals can be more difficult to ignore. They experience ongoing physical and emotional stress. They are physically mutilated. And they are deprived of the diet they would normally eat. All of the animals are prone to infection, resulting from the lack of exercise and sunlight, forced confinement, abnormal crowding, and

the concentrated amounts of urine and manure in their living quarters.

The concentration of manure in these huge conglomerations is the rationale that factory farmers use to routinely give their animals antibiotics. But this practice is backfiring. For example, the summer of 2007 brought alarming reports of infections of methicillin-resistant *Staphylococcus aureus* (MRSA) in the meat of factory farmed pigs, chickens, and (to a lesser extent) cattle. In the Netherlands alone, the MRSA strain was found in 20% of pork and 21% of chicken. Now MRSA has spread worldwide. Another problem with antibiotic-fed animals arises when their manure is used as fertilizer. The drugs are excreted in the manure and the plants absorb the drugs, which become concentrated in the leaves and especially the roots. This has huge health ramifications for people who eat potatoes, beets, and carrots. Such manure is legally permitted to be applied to organically grown crops, even though the smaller farms tend not to use it.

The environmental damage from factory farmed manure is severe. In a diverse ecosystem, the animals' manure is naturally recycled. In mega-farms, the manure spills into nearby lakes, streams and underground springs, thus encouraging the rapid growth of algae and bacteria.

Slaughtering techniques are similar for all factory farmed animals. According to US law, pigs, chickens and other animals must be stunned (via electroshock or a mechanical blow to the head) before being hung upside down by their back legs and bled to death. But too often the animals aren't sufficiently stunned because the workers aren't given enough time. The animals remain conscious as they're knifed and cut to pieces. Their kicking and struggling then injures the workers who are trying to kill them. (Slaughterhouse workers suffer the highest rate of injuries of all manufacturing employees.) Slaughtering a pig can be especially difficult. If it can't be killed with a knife within the allotted time limit, the worker must still carry it to the next station on the assembly line—a scalding tank—where the fully aware pig is boiled alive.

The high levels of fear and terror in these animals skyrocket when they're slaughtered. The stress hormones they release travel to their muscles, and we ingest these hormones when we eat the meat.

Please note that I am not trying to promote a vegetarian agenda. My intention is to point out that factory farming causes undue suffering for the animals, and this suffering eventually becomes part of our meals—and our very cells.

Now let us briefly examine a few more details of the living conditions unique to each animal that supplies us with protein.

The road to healing begins when we all feel deep concern for the suffering that surrounds and suffuses us all with the darkness of a dying planet. We have made the Earth so sick—and ourselves in the process—because we have lost touch with the sacred dimensions of reality, of nature, of wholeness, balance, harmony, health and spiritual well-being.

We are so spiritually disconnected that we find reason to put our own genes into pigs so that we can use their hearts and other organs to replace our own diseased organs, which have in turn been harmed by our excessive consumption of animals raised in horrendous conditions and the ongoing pollution of the environment and our vital food chain.

We are so cognitively disconnected from reality that we spray poisonous chemicals on the crops we feed to our children and rationalize such stupidity as the best and most efficient way to feed a hungry world and even to protect wildlife and biodiversity.

We are so emotionally disconnected from other animals that for economic reasons we justify incarcerating livestock in the cruel, intensive confinement systems of factory farming, and accept the suffering of other animals in vivisection laboratories in the name of medical progress. To question this pathology of anthropocentrism is not to put animals or nature before people, but rather to demand a full ethical and economic accounting of those activities, values and policies that are harmful to the life community.

Birds. Chickens and turkeys are kept in cages that are so cramped, the birds peck at each other in frustration. This is why their beaks are clipped (without anesthesia). Additionally, the claws of turkeys are clipped to prevent them from attacking each other. Often the cages are stacked one on top of the other, from floor to ceiling.

Urine and excrement abound. When there are no cages, the birds wade through this mess on the floor. The ammonia fumes from the waste are so strong, the chickens develop severe respiratory lesions and gastrointestinal tract disorders. “The livestock sector,” reports one source, “produces an estimated 73% of all ammonia emissions nationwide.” The United States Environmental Protection Agency lists ammonia “alongside arsenic, cyanide, and benzene as hazardous substances. . . .”⁵⁵

Arsenic, added to the chickens' feed to kill intestinal parasites, is not excreted. It remains in the chickens and ends up on our plates. The food factories don't give workers enough time to remove all the feces from the

poultry, so all birds are dipped in a bath of carcinogenic chlorine bleach to sterilize them.

Sometimes the bones in the chickens' legs become abnormally soft and the muscles turn weak, making it impossible for the birds to walk. However, these diseased and dying birds are seldom discarded. When they're processed, the overtly bad portions are simply cut off and thrown away, and the apparently normal parts are sold. Damaged and diseased birds are largely the source of the "one type of chicken part" packages available in commercial supermarkets.

Due to consumer demand for white meat, factory farmed chickens and turkeys have been bred, and sometimes genetically engineered, to have excessively plump breasts. (The section on genetic engineering starts on page 288.) Carrying this extra weight is abnormal for the birds. Turkeys have been altered so much that they cannot even breed as they normally would, so the females must be artificially inseminated.

Birds that are not factory farmed, or descended from factory farmed birds, are structurally quite different. They are not only sturdier, they function better too. Heirloom animals and plants will be discussed shortly.

Eggs. Factory farmed eggs come from factory farmed chickens. The farmers trick the chickens into laying more eggs by keeping them under artificial lights for at least 17 hours a day. Whereas one free roaming chicken will lay one egg about every other day (and fewer during cold weather), one caged, factory farmed chicken will lay 300 eggs a year.

Foie Gras from Ducks or Geese. Translated literally from French as *fatty liver*, foie gras is a pate (mash) traditionally made from the enlarged livers of geese, and more recently, ducks as well (which are easier to raise than geese). Foie gras is expensive, and considered a delicacy. Ducks only a few months old are confined to a dark shed, and force-fed excessive amounts of food several times a day via a feeding tube thrust down their throats directly into their gullets. The liver, unable to handle that kind of overfeeding, becomes pathologically enlarged, usually about 8 or 10 times its normal size. Such ducks become obese, and stand, walk and breathe with difficulty. They suffer from throat lacerations, and from bacterial and fungal infections in their digestive tracts. Many die prematurely.

Swine. This term covers pigs and hogs—which are simply larger pigs, weighing more than 120 pounds (50 kilograms)—that are raised for ham, pork, and bacon. These animals lead wretched lives. Breeding sows are subject to continuous impregnation via artificial insemination, and are confined in 2-foot-wide gestation crates that prevent them from turning around or

lying down comfortably. The crates to which they are transferred to give birth have barely enough room to stand up and lie down. With no straw or other bedding, many develop sores on their legs. (Currently, some US states are creating laws that forbid the use of breeding crates.)

When the piglets are young, notches are cut into their ears for identification. Their tails are also cut off—all done without anesthesia or pain relievers—to minimize tail biting, a neurotic behavior due to their agitation over being confined. Fifteen percent of all piglets die by the age of three weeks. The survivors are taken away from their mothers and crowded into pens with metal bars and concrete floors. Pigs are confined until they reach the weight of 250 pounds at six months of age.

Pigs are inherently clean animals. When allowed to roam outdoors in humane conditions, they roll in the mud to keep cool. Given enough space, they are careful not to soil their eating and sleeping areas. But factory farms force them to live in their own excrement and vomit. Sixty percent of pigs have severe respiratory problems due to the dander and noxious fumes from the urine and feces that build up inside the sheds. They also suffer from arthritis (due to their unnaturally rapid growth rate, lack of exercise and excrement-covered floors); parvovirus; and various gastrointestinal diseases including salmonella.

Pigs and hogs conventionally raised for consumption in the US are routinely given a growth enhancer drug called *ractopamine*. The drug's effects include tachycardia (elevated heartbeat), enlarged heart, respiratory disorders, bloat, lameness, muscle stiffness, hyperactivity, aggression, and death. Birth defects—missing digits and abnormally short limbs—have appeared in test animals. Since other countries banned its use, growers in the United States haven't used it in exported meat; but the drug has been approved in the US and is used freely. Ractopamine is also fed to cattle, who then develop hoof problems (the hooves simply fall off the animal). Turkeys are fed the drug as well. Despite being sued, the FDA has refused to release records pertaining to the drug, which so far has been tested by Codex (the United Nations "food standards" organization) on only six humans—one of whom left the study due to adverse effects.

Cattle. Of all factory farmed animals, adult cattle raised for beef have the easiest lives. Because of their size they must live outside in their natural surroundings. During this time, the most serious violation they must endure is probably branding, where a piece of hot iron is seared into their flesh for identification purposes. For identification, many cows wear ear tags of plastic or metal that pierce their ears. Some of these tags are electronic, emitting frequencies of 125 KHz or higher for tracking purposes.

Before being transported to slaughterhouses in cramped trucks, most cattle are first taken to feedlots to gain more weight. Factory farmed cattle are usually fed genetically engineered grains, manure from chickens and other animals, slaughterhouse waste, and even garbage (including sawdust, cardboard and newspaper).

Dairy cattle are routinely fed rBGH (recombinant bovine growth hormone). It artificially creates a larger milk yield but also makes the cows ill, causing pain and discomfort due to increased swelling of the udder. This in turn promotes infection, which leads to an increase of pus and blood in the milk that the cows provide. These biological wastes, plus developmental abnormalities, are then passed on to anyone who eats the milk products. (See Chapter 1 for more information on rBGH and its effects on both cows and humans, and for information on the media's attempt to conceal its dangers.)

The social costs of factory farmed foods are high. Crops are usually picked by workers who live in substandard conditions and are not paid a living wage. Often the crops are irradiated (described on page 290). Meats are butchered in giant warehouses under inhumane conditions, both for the animals and for the workers who slaughter them. The workers often become injured due to the high rate of repetitive motion involved in processing animals at breakneck speed. In the United States, many workers hired as food processors are illegal immigrants who don't protest against filthy and dangerous conditions because they fear that they will simply be replaced. (Apparently, both animals and humans are considered expendable.) Although the US government has been more diligent recently in investigating the hiring of these workers, conditions have not improved much.

Calves (Veal). The marketing phrase “milk fed” refers to commercially raised calves, which produce veal. Adhering to an increasingly common practice of language reversal, the phrase means exactly the opposite of what the dictionary (and common sense) would indicate. Young calves are confined to pens that do not allow them to turn around or lie down. They are separated from their mothers at an early age and are not allowed to nurse. This nutrient-deficient diet is administered purposely to make them anemic, which gives their flesh an abnormally tender texture after they are slaughtered. Organically raised or grass fed calves are never called “milk fed”; they *are* fed milk—which makes them, and us, healthier.

Conventionally Grown / Raised

In common usage, *conventional* means “customary,” “commonplace,” “predominant” or “prevailing”—in other words, what the dominant or mainstream culture has

decided is normal or right. This is simply a more benign way of saying “factory farmed.” The food industry doesn't want to remind consumers of the dangers of factory farmed food—the dangers of ill health for the animals, for the people who eat the animals and produce, and for the employees who are forced to process these products under substandard working conditions. Using the word “conventional” helps to soften the implications of what people are eating when they choose factory farmed animals and plants.

Farm Raised

This legal term pertains to fish. The most popular farmed fish include bass, carp, catfish, tilapia, trout, shrimp, and salmon. I will discuss salmon in detail because it's so toxic.

Farmed salmon are grown in small floating cages in rivers and oceans. The pens are crowded, which increases the incidences of disease. To deal with infection, salmon growers routinely feed antibiotics to the fish along with their food—more antibiotics for their weight than any land livestock. The salmon's feed is also contaminated with over a dozen dioxins and industrial chemicals. Normally, salmon in the wild turn orange-pink due to the high amounts of krill (a tiny shrimp) they eat. Denied their usual diet, their flesh turns gray. This is why the pellets of grain and other ingredients they are fed are laced with bright orange dye. The amount and hue of the dye is based on a survey conducted by the fish industry to determine which shade of orange seemed the most “natural” to consumers, and thus the most appealing.

Farmed salmon causes other problems too. Depending on which source you believe (the US Department of

Humane Slaughter

The animals we raise for food deserve to have not only peaceful and comfortable lives, but also peaceful and comfortable deaths. To accomplish this, Dr. Temple Grandin has been designing humane cattle butchering plants for decades. In her books and lectures, Grandin describes growing up autistic: perceiving the world in pictures (rather than words), and being easily overwhelmed by stimuli that most people can ignore. In some ways, Grandin's neurological wiring and information processing are similar to that of animals, giving her profound insight into how cattle respond to their environment. Thanks to her genuine love of cattle, the animals can spend their final moments feeling calm instead of terrified. Grandin's facility designs and cattle handling techniques are used in slaughterhouses all over the world.

Agriculture or the World Health Organization), the farmed Atlantic salmon contains 70% to 200% more fat than wild Atlantic salmon because of the high fat content in their feed. These fats are the more common Omega 6s, not the less common (and more healthful) Omega 3s.

Farmed salmon pose serious danger to wild fish. Crowded together in large numbers, the artificially raised salmon accumulate abnormally high levels of excrement in very small areas. Farmed salmon infect their wild counterparts—which may live near the cages or merely swim past them—with parasites and other infectious diseases that ordinarily don't plague the wild fish. Increasing numbers of farmed salmon are being genetically engineered (see "Genetically Engineered or Genetically Modified" in the next column). Despite the denials of the farmed fish industry, GE salmon can—and do—escape from their cages. Once in the open water, they mate with wild fish. The resulting offspring are often malformed or sterile. Farmed salmon are now endangering the entire wild salmon population.

Wild salmon is highly nutritious. The types of Pacific salmon that usually aren't farmed are sockeye, chum, and pink. However, this may change, so check with the fish seller to be sure.

Genetically Engineered or Genetically Modified

Genetic engineering involves the splicing of genetic material from a plant, animal or even human tissue, into the plant being manipulated. The phrase *genetically modified* (GM) is interchangeably used with *genetically engineered* (GE), while the acronym *GMOs* stands for the *genetically modified organisms* that are used to make GE/GM plants. GE plants are extremely dangerous—to humans, animals, and the environment. The most prevalent genetically engineered crops are corn and soybeans, although many more plants, including potatoes, rice and apples, have been produced on a smaller scale.

The genetic engineering of plants (and animals) has been done for decades. In the early 1970s, scientists discovered how to transplant genes between different biological species and created the first GMOs. In 1975, a secret conference was held in the US to discuss how genetic engineering should proceed. One year later, the National Institutes of Health produced guidelines for genetic modification research. To give just a few highlights of that research: technicians produced a GE pig in 1985, a mouse carrying human genes in 1987, the first GE corn in 1988, and a tobacco plant that produced hemoglobin (a human blood protein) in 1995. By the

The Mechanics of Genetic Engineering

Ordinarily, when humans produce new varieties of crops, they place the pollen of one plant onto a related plant to produce a new variety (called *hybridization*). Or, they place two similar animals in a pen and hope that they mate. But genetic engineering is completely different. It's "the process by which genes are altered and transferred artificially from one organism to another," writes Environmental Research Foundation consultant Rachel Massey. "Genes, which are made of DNA, contain the [biochemical] instructions according to which cells produce proteins; proteins in turn form the basis for most of a cell's functions. Genetic engineering makes it possible to mix genetic material between organisms that could never breed with each other."⁵⁶

In *Trust Us, We're Experts*, Sheldon Rampton and John Stauber point out that genetic manipulation is "frequently described as 'gene splicing,' a term that obscures much of the uncertainty and imprecision of the process." It evokes images of splicing a piece of film, which is easily seen and rearranged. However, one commonly used technique uses a patented "gene gun" that shoots tiny metal DNA coated slivers from one organism to another. "No one can predict where the new gene is going to land within the genome of the targeted organism. It may attach to the site of any chromosome, or may attach in the middle of another gene and interfere with the normal functioning of the cell."⁵⁷ Hungarian research biologist Arpad Pusztai analogizes this process to putting a blindfold on the archer William Tell before he shoots his arrow at a target.

It's more than crops that are bioengineered. So is a new type of lawn grass (that presumably won't need to be mowed much). However, this grass is outside the jurisdiction of the US Agriculture Department; so even the small amount of regulation that GE plants might have is non-existent in this case. The creators of the grass used a legal loophole in the law by inserting foreign genetic material from *other plants* into the grass instead of bacteria or viruses. A company executive stated: "If you take genetic material from a plant and it's not considered a pest, and you don't . . . sort of violate the rules, there's a bunch of stuff you can do that at least technically is unregulated."⁵⁸

Proponents of GE foods claim that there's no difference between splicing genes in a laboratory and cross-breeding plants, but this is not true. In the laboratory, scientists are crossing the species barrier by mixing together genetic material of animals, plants, and microorganisms. Human genes in tobacco, fish genes in tomatoes, viruses in squash and fruit, etc., would never be found in Nature. The natural world limits the negative effects of cross-pollination and cross-breeding by ensuring that only related plants or animals can accept each other's sexual seed (pollen or sperm).

mid-1990s, the biotech company Monsanto introduced “Roundup-Ready” soybeans to make them more resistant to its herbicide Roundup® (which gave Monsanto an opportunity to sell even more Roundup®). In the year 2000, GE StarLink™ corn—which contains a built-in pesticide and had never been approved for human consumption—crept into the human food supply. Across the US, people who ate contaminated tortillas and corn chips reported headaches and digestive disturbances, due to the product’s indigestibility and high pesticide levels. The US government bought all the GE corn-contaminated lots to save the businesses involved from financial ruin; but the funds came from the pockets of taxpayers. Safe-food.org reported, “There are about 40 varieties of genetically engineered crops approved for marketing in the US. As a result, 60% to 70% of the foods on your grocery shelves contain genetically engineered components.” (Other sources give a higher figure of 75%.) “Genetic engineering is the largest food experiment in the history of the world. We are all the guinea pigs.”⁵⁹ (See Sidebar, “The Mechanics of Genetic Engineering.”)

In March 2017, a federal lawsuit against Monsanto revealed that an Environmental Protection Agency official helped promote Roundup® as safe, while deliberately withholding Monsanto’s own data showing that glyphosate causes cancer. Also revealed was a note to the corrupt official by Marion Copley, a now-deceased EPA toxicologist, who accused him of burying the damning evidence.

Glyphosate is the main ingredient in Roundup®. The “gly” in glyphosate stands for *glycine*, an amino acid used by the body to make proteins that are found in high concentrations in the skin, joints, muscles, and connective tissue. Glyphosate contains a glycine analogue that latches onto the body’s glycine receptor sites instead of the real glycine. Thus, when glyphosate is ingested, the body creates counterfeit proteins that are completely nonfunctional—resulting in severe cellular and tissue damage. Christopher Portier, one of the lead scientists who conducted the World Health Organization (WHO) study on Roundup®, has publicly stated that glyphosate causes genetic damage that can lead to non-Hodgkins lymphoma, lung, and other cancers. Glyphosate causes a fatal kidney disease due to its ability to attract heavy metals. It binds to manganese and other vital minerals, preventing the body from utilizing them. It promotes aluminum absorption, which contributes to or outright causes dementia and autism. And glyphosate creates the neurotoxin formaldehyde when it degrades. Roundup® is one thousand times more toxic than glyphosate alone, because the petroleum and other poisonous compounds it contains interact together in a hazardous way. If you eat GE crops, you ingest even more toxic pesticide than if you ate conventionally sprayed, non-GE crops. All pesticides migrate to inside the plant, so washing the surface does not

totally eliminate the poisons. GE crops are so poisonous, their exceptionally poor nutrient content is irrelevant.

Some GE crops contain built-in drugs such as vaccines, forcing people to ingest unsafe drugs that they might not need or want. GE tomatoes contain genes from a cold-water fish (ostensibly to make the tomato more resistant to freezing and thus allowing for a longer growing season). But this forces consumers—including vegetarians and those with fish allergies—to ingest fish proteins along with their tomatoes. To add a cannibalistic note, human liver genes are now found in rice. (The gene was presumably added to help us digest the pesticides used on the rice.)

These bizarre genetic experiments, rightly called “Frankenfoods” by critics, inflict unthinkable damage on humans, animals, other plants, and insects: chickens with four feet, calves and goats with two heads, piglets with wafer-thin skin. A gene for human growth hormone causes pigs to become skinny, cross-eyed, and arthritic. When spliced into salmon, the growth hormone gene makes them grow too big, too fast. And it turns them green. Farmed salmon escape from their pens into large

bodies of open water, contaminating wild fish populations.

Monarch butterflies and ladybugs that consume pollen from plants engineered to produce the toxin from the *Bacillus thuringiensis* bacterium become sick or die, as do birds that eat the contaminated insects. In the past few years, beekeepers worldwide have reported losing between 60% and 70% of their bees. We now know that GE crops—and the toxic pesticides so freely sprayed on them—are partly responsible for the disappearance of the bees (called “Colony Collapse Disorder”), due to impaired memory, loss of navigation ability, and poor immune response. A four-year study by German zoologist Hans-Hinrich Kaatz showed that an alien gene used to modify some strains of canola had transferred to bacteria living inside the guts of honeybees. In a similar way, GE bacteria contaminate the beneficial bacteria in the human digestive tract. The intestinal flora aid with digestion, immunity, blood clotting, and other important functions. The DNA of humans who eat genetically contaminated produce is permanently and negatively altered, as is the DNA of the animals that are fed GE crops.

Livestock farmers report that, given a choice, their cattle walk away from GE grain and instead go to the non-engineered batches. They only eat the GE feed if they’re starving. Apparently, animals have more sense than many humans.

A Quick Guide to GE Crops

Corn. In the US, the federal government subsidizes the growing of corn, making it the foremost GE crop grown. GE corn is used mainly as animal feed, but it has gotten into the human food supply.

Soy. Even when raised organically, soy is problematic to eat (unless fermented for over two years), is most often GE. The oils, protein supplements and emulsifiers into which it's made, are also genetically modified unless labeled otherwise.

Yellow Crook Neck and (green) Zucchini Squash. Not many of these squashes are GE, but it's worth buying organic to make sure you don't ingest foreign proteins.

Alfalfa. Despite opposition from consumers and organic farmers, alfalfa became genetically engineered in 2011. Cows fed GE alfalfa suffer from abnormally high digestive disorders and parasites.

Canola. About 90% of canola from the US and Canada is estimated to be genetically engineered.

Sugar Beets. More than half of the sugar sold in the US comes from sugar beets, not sugar cane; and of the beet sugar, at least 90% is GE.

Cottonseed. The genetic engineering of cotton affects more than the clothes we wear. Cottonseed oil is routinely used in chips and bakery items.

Papaya. This amazingly versatile fruit, whose enzymes heal wounds, has been ruined in Hawaii, where 75% of the papaya crop has been GE.

Upcoming: apples, trees, and more.

Seeds are spread by the wind and birds, and pollen is transferred by insects. It's nature's way of helping plants propagate. But many farmers who choose not to use GE seeds are finding that their corn, wheat, canola and other crops are becoming contaminated anyway, because nothing can stop the wind from scattering pollen from GE fields to non-GE fields. Glyphosate resistance has even been transferred to weeds. Glyphosate-resistant weeds are proliferating all over the world: horseweed in several areas of the US; rigid rye grass in Australia; goose grass in Malaysia; and various other plants in Canada.

A press release, issued worldwide in the spring of 2006, described how 1,820 sheep in New Zealand had died after grazing on land where GE cotton had been grown. "The sheep and goats started dying after seven days of continuously grazing on tender leaves and pods of Bt [GE] cotton that remained in the fields after picking," the report stated. "Even wearing GE cotton could cause terrible skin reactions. . . . Workers picking GE cotton suffered severe skin reactions with itching and blistering eruptions leaving

a black skin discolouration which was still apparent after five months."⁶⁰ Currently, many scientists believe that the mysterious new condition called Morgellon's disease—where living, parasitic strands of fibers emerge from the skin, causing severe skin eruptions and neurological damage—may be at least partly related to wearing clothing made from GE cotton.

Most people, worldwide, are actively opposed to eating GE produce and animals. In the US, consumer groups are demanding compulsory GE labeling. However, the Grocery Manufacturers Association of America has donated hundreds of thousands of dollars to help defeat laws that would require such labeling. If consumers knew what they were really buying, there would no longer be a market for GE produce and GE animals, and company profits would dwindle. Most countries in the world have made GE crops illegal. China and Africa have even refused GE-contaminated shipments of US corn.

Unless you buy organic produce or trust the farmer who supplies your food, supermarket or restaurant food are likely genetically engineered. So, if you haven't eaten organic foods on a regular basis but are thinking of starting, now is the time. A good way to avoid even accidentally GE contaminated foods is to eat less popular produce that industry has not tampered with (because there is no money to be made in less popular varieties). This means consuming less familiar vegetables, or, if you eat corn, blue corn or popcorn (different species) instead of white corn.

Monsanto (recently merged with Bayer) was then given permission to use the more favorable word "biofortified" instead of "genetically engineered." Don't be fooled.

Irradiated

Irradiation consists of bombarding foods at high speeds with gamma rays from Cobalt 60, Cesium-137, or other radiolytic (radioactive) substances, some of which can remain radioactive for 600 years. Almost everything you buy in the supermarket—meat, poultry, eggs, fruits, vegetables, spices, nuts, seeds, grains, processed and baked goods—is irradiated.

The rationale for treating foods in this manner is to prevent spoilage from bacterial contamination and infestation by insects. But in truth, the practice was originally promoted by the nuclear power and nuclear bomb industries, which needed a way to get rid of their nuclear waste. These industries not only succeeded in creating a venue for their waste material, they also reaped a profit by creating a marketplace "need" for something that consumers would never think to ask for. The FDA has legalized irradiation, ignoring the growing body of research showing that this process alters the texture of foods; destroys nutrients such as enzymes and Vitamins

A, B, C, E and K; creates poisonous byproducts such as benzene, formaldehyde and nitrosamines; and makes the food carcinogenic due to the change in its molecular structure. (All these effects are similar to those caused by cooking food in a microwave oven, discussed shortly.)

There is also the danger that bacteria exposed to the radiation may develop a resistance to it, and eventually become more dangerous. This is similar to the resistance that bacteria develop from the over-consumption of antibiotics. Ironically, even though bacteria might be killed, their excreted wastes remain in the food.

Not all foodborne pathogens are killed by irradiation. The hepatitis and Norwalk viruses are unaffected. Studies have also shown impaired reproduction and more deaths in animals fed irradiated food. Proponents freely admit that irradiation accomplishes the intended objective of preventing seeds, nuts and grains from sprouting. But think about it: this means that there is no longer any enzyme activity or vitality left in the food! Enzymes are discussed in more detail later in this chapter.

Don't be fooled if you see products marked *cold pasteurization* or *electronic pasteurization*. The food industry uses these terms instead of "irradiation" to persuade consumers that the practice is harmless. Likewise, the FDA terms this atrocity *radiant energy* to make it sound lovely, like sunshine or a fireplace. Newer irradiation techniques use electron accelerators, which cause radiation levels that are equivalent to those produced by up to 70 million chest X-rays. These X-rays can pass through plant cells and break apart the cell walls.

In February 2001, the World Health Organization (WHO) decided to increase the maximum allowable radiation levels for food to the equivalent of 330 million chest X-rays—2,000 times the fatal radiation dose for

humans. WHO claimed that this level is safe. It's no wonder that opponents of irradiation call it "nuking"!

Irradiation opponents point out that if more attention were given to producing food that is grown locally (thus decreasing its shipping time), stored properly, and processed cleanly in the first place, there would be no need to prevent spoilage by nuking it. Meats are prone to becoming highly contaminated with *E. coli* because in the slaughterhouses, the intestines are punctured and feces spill onto the meat. Even though an official food radiation logo exists, it's not routinely displayed in supermarkets or on packaging. Therefore, consumers have no idea what they are buying. The best way to avoid ingesting radioactive waste with your food is to buy from a source you know and trust.

Cloned

"Simply put," reads the website of the Organic Consumer's Association, "cloning is a way to make genetically identical copies of an animal without using sexual reproduction. DNA is taken from one of the animal's cells and inserted into an unfertilized egg whose own DNA has been removed. The egg is then placed inside a surrogate mother."⁶¹ After being shocked by chemicals or electricity, the egg divides as though it were fertilized by a sperm cell from a male of the species. The baby that is eventually born is an exact genetic duplicate of the animal that donated the cloning cell.

Animals that are created by cloning tend to be unusually large fetuses, which can lead to the death of the mother carrying the fetus. The animals also have damaged and abnormal cells that lead to premature aging; deformities of the head and limbs; and problems with the heart, lungs and other organs. "But even if two animals have identical

MSG is Sprayed on Our Crops

In January of 1998, the United States Environmental Protection Agency approved a spray called Auxigro® for use on *all crops*—fruits, nuts, seeds, grains and vegetables—as they grow. The spray, which is approved as a drying agent, disinfectant, fertilizer, fungicide and growth regulator, contains 29.2% glutamic acid, or MSG. Produce can be sold without bearing a label that it was sprayed. MSG is even being applied directly on crops used in baby food, despite the fact that in the 1970s, baby food processors were persuaded to omit MSG from their many products and in 1995, the FDA proposed that free glutamic acid be labeled due to its potentially deadly effect on individuals with asthma. The EPA website states: "Waivers have been requested for acute toxicity, genotoxicity, reproductive and developmental toxicity, subchronic toxicity, chronic toxicity, and acute toxicity to nontarget species. . . ." ⁶² In other words, even though MSG can cause grave damage (and even fatalities) in humans and animals, consumers don't deserve to know about it, and the companies using the chemical aren't obliged to inform the public.

MSG remains on our food, diffuses into the air, and trickles into our groundwater. (See Insert, "The Truth About MSG," on page 343.) Fortunately, Vitamin C (ascorbic acid) protects from glutamate damage. Some practitioners suggest that for every 30 pounds of body weight, take a minimum of 50 mg of Vitamin C between 15 and 30 minutes before ingesting the MSG-laden food. However, the best protection is avoidance. Buy organic.

Common sense tells me organic is better . . . than the kind grown with organophosphates, with antibiotics and growth hormones, with cadmium and lead and arsenic (the EPA permits the use of toxic waste in fertilizers). . . . Pesticide residues are omnipresent in the American food supply. . . . Many of them are known carcinogens, neurotoxins and endocrine disrupters. . . . The government has established acceptable levels for these residues in crops, though whether that means they're safe to consume is debatable: in setting these tolerances, the government has historically weighed the risk to our health against the benefit to agriculture. The tolerances also haven't taken into account that children's narrow diets make them especially susceptible or that the complex mixtures of chemicals to which we're exposed heighten the dangers.

genes," write the authors of a *New York Times* article, "they can turn out differently if those genes are turned on or off at different times. And studies have shown that patterns of gene activity are different in embryos created by cloning compared with embryos created by the fusing of sperm and egg."⁶³ That is why so many clones die during gestation or soon after birth.

Despite consumer objections, in the United States cloned animals in our food supply are neither regulated nor labeled by the Food and Drug Administration. Due to the problems with cloning, it still remains a high-priced method of "food" production; and it's difficult to say how many packages of meat found in supermarkets (mostly beef at this point) are actually from cloned animals. However, some farmers who want to continually perpetuate their prize animals support this method.

Organic

The original legal term, which was set up by the United States Department of Agriculture (USDA), outlined the following conditions. Vegetables, fruits, grains, seeds, nuts and oils must be grown without synthetic pesticides or herbicides, chemical fertilizers, irradiation, or other contaminants. Animals raised for food (and their dairy and egg products) must eat only vegetable materials grown in accordance with organic standards. In addition, the animals themselves must not be given hormones or routinely fed antibiotics (although they are permitted antibiotics if they become ill, as long as the medication is withdrawn a certain number of weeks before the animals are slaughtered).

These standards are acceptable. The problem is, in the past several years conventional food growers—

with the support of the USDA, FDA and the Grocery Manufacturers Association—have tried to dilute organic standards, which would allow organic foods to be heavily contaminated and make the label useless. (The Grocery Manufacturers Association has also infiltrated the Organic Trade Association, which is supposed to certify organic foods.) Attempts have been made to pass bills that allow sewage, irradiation, pesticides, synthetic fertilizers, non-organic and GE feed, chlorine and other chemicals, and even factory farmed animal intestines to be used in the growing of food labeled "organic"! These attempts may or may not succeed; so be sure to stay informed about these schemes to undermine our food supply.

Another dilution of organic laws (at least in the US) is the inclusion of hydroponic plants (raised in water, not soil) and aquaponic plants (raised in water with fish). Food raised in soil contains beneficial microorganisms that are absent in water. Organic is synonymous with "grown in soil." As these sabotage attempts continue, the public will have to object even more loudly if we want our food to remain edible and healthful.

Be aware that some farmers do raise crops and animals organically that are not certified as organic. The farmers can't afford to pay the inflated certification sums required by the government, can't devote large numbers of hours to complete the burdensome paperwork, and can't afford to pay someone else to do the paperwork. Thus, many reluctantly choose to exclude themselves from this classification system. If you know the farmer and trust his or her growing methods, a government certification may not be important. And, if bills are passed that make organic standards meaningless, government certification will not be necessary or desirable anyway.

Wildcrafted or Wild

This term is used mostly for herbs, but can also pertain to fruits and some vegetables. It indicates that the plant has been growing in its natural location, rather than rooted in a garden or farm, that it has not been domesticated, and that it's very likely unsprayed. By definition, wildcrafted herbs are "found" plants, so their numbers can dwindle. Therefore, the people who pick these plants are usually careful to limit the number they take. A good reason to leave some plants is to allow bees and other pollinators access to them, and thus help propagate more plants.

Heirloom or Open-Pollinated

This usually refers to vegetables, although it can also describe other plants and (in the case of *heirloom*) animals. An heirloom plant is hardly ever used in monoculture agribusiness, which relies on hybrid plants to achieve uniformity and consistency. Normally, a hybrid plant is

created by grafting one plant onto another, or by manually mating dissimilar types of plants over many generations to obtain certain desired characteristics. This makes subsequent generations of plants grown from those seeds unstable because the farmer cannot be sure if succeeding generations will have the same (desired) characteristics of the parent plant. Sometimes, the descendants of hybrid plants are sterile; they cannot produce seeds at all.

In contrast, an heirloom fruit or vegetable is open-pollinated. The plant has access to open air, where bees and birds that feed on the nectar, fruit and seeds spread pollen from one plant to another. The plants produced in this manner are always seed-bearing. Also, the seeds they produce will always produce plants just like them—a guarantee that’s impossible to obtain with hybrid plants. Moreover, heirloom plants are hardy and resistant to disease and pests. This is due to the ability of heirlooms to adapt over time to the climate and soil in which they grow. They might not be as conventionally pretty or uniform as hybrids, but the greater environmental adaptability of their gene pool gives them a more varied and interesting appearance and a far better taste. I personally prefer the taste of heirloom produce—even when not specifically stated as being organically grown—to organically raised crops that are not heirloom varieties.

Special strains of cattle, sheep, and other animals that have not been over-bred, are generally smaller than their commercial counterparts, and are not used much for the commercial market, are *heirloom*. Often, the hardest, most flavorful meats are from heirloom animals. Heirloom chickens and turkeys have not been bred to have abnormally large breasts. Such birds are healthier and more resistant to disease because structurally they are stronger. They take more time to raise because they don’t gain weight prematurely, but this also makes them superior in taste to factory farmed and even organic animals.

Unsprayed

Unsprayed is not a legal term, so it can’t be legally guaranteed. Only organically grown crops can be certified as unsprayed. However, if you trust the grower, eating unsprayed produce can be as safe as eating organic. The produce may even be fresher, because it’s probably from a farmers’ market that requires the produce to have been picked within the last 24 hours. See “Local,” below.

Local

Local, while not a legal term, has retained its common meaning because it has not been legally co-opted and altered by government. (Bureaucrats often reverse the meanings of common terms so they mean the opposite of

what we think they mean.) Local fruits, vegetables, and herbs are produced by farmers living within a few hundred miles of your area. Farmers sell either to neighborhood stores, or set up stalls at farmers markets in neighborhood parks, parking lots, and other open areas. “Local” doesn’t indicate how the crops are grown (including whether they are organic). However, buying local is often an opportunity to ask questions of the farmers, including what (if any) sprays they use. More people are beginning to request locally grown produce because it can be picked ripe and is fresher than produce trucked from farther away. Buying local supports small farmers. Also, shipping food over shorter distances saves fuel.

Free Range

Used for poultry, these terms are misleading. Even if the chickens aren’t in cages and are technically allowed to walk around, the space in which they are confined is a crowded indoor shelter with no room to walk. If they do walk, they are forced to step on another bird, so this can hardly be called “freely ranging.” Access to sunlight is usually minimal, less than 30 minutes a day. Often, the birds are exposed solely to artificial fluorescent lighting.

If these terms are used for eggs, typically the laying hens are kept in cages. However, the yolks of true free range (or cage free) eggs have a deeper yellow or gold color than the yolks of factory farmed eggs. Free range yolks are also firmer, and sit higher after being poured from the shell. The shells may be harder, due to increased calcium levels.

Cage Free

Although the birds aren’t in cages, their living conditions could still be crowded—similar to free range (above).

When Organic Isn’t Necessary

It’s very expensive in the United States to certify food as organic, so not all naturally-grown food is certified. However, even though uncertified food cannot legally be called organic, it can still be clean.

Some foods labeled “organic” provide little or no advantage. For instance, virtually all imported olive oil is clean. In sunshine-filled Greece and Italy, farmers would never dream of spraying their crops (nor would they have any “need” to do so).

Today, on this heavily polluted planet, even organically raised produce contains some pesticides. Toxic pesticides are now found in the fat of sea mammals at the formerly pristine North Pole; so there is no completely clean animal, plant, soil, water, or human being anywhere in the world. The best we can do is to eat the cleanest food as much as possible.

The Most Heavily Sprayed Fruits and Vegetables

The samples tested in the left hand column were scored according to *how many* contained detectable pesticides, the average *amount* (in ppm) of all pesticides found, and the *number of total pesticides* found on the crop. It's unclear how the right hand column was scored. Unfortunately, available data for 2017 lists fewer crops than in 2006. Incidentally, according to a 1992 EPA journal, only one-tenth of one percent of a given pesticide, sprayed onto a crop, reaches its original target. This means that the air is constantly saturated with pesticides, which we breathe.

All Natural

This is not a legal term, but a huge consumer scam. To most people, the rosy-sounding word *natural* conveys “being in nature,” with the image of an animal happily frolicking in the sun with the rest of its herd or flock—the very antithesis of factory farming. However, the food processor is not legally bound to adhere to such “natural” practices, and instead relies on the consumer’s imagination and desire to impart a positive meaning to the phrase. Note how many times you see “all natural” on a label.

Naturally Raised

This is not a legal term. Food processors deliberately use it, though, knowing that uninformed consumers will imagine barns of healthy, happy, chemical-free animals—the exact *opposite* of how these animals are actually being raised. Sometimes, cattle ranchers (to their detriment) use the term to mean *grass fed*, which is specific and has a much different meaning. See below.

Grass Fed

This pertains to cattle, calves, lambs, sheep, buffalo, goats, and other ruminant mammals (*ruminants* have compartmentalized, multi-chamber stomachs) that chew their cud. Note that grass cannot be certified organic. Because it’s difficult to prevent a grazing animal from seizing something from the earth that’s not legally labeled “organic,” meats designated “grass fed” cannot also be organic. However, in this case the label “organic” is no advantage. Organically raised animals are usually fed grain, which causes problems (see “Vegetarian Fed or Grain Fed,” next).

Grass fed meats are even better than organic meats. The animals are healthier and stronger because they’re raised outside in their native environment and allowed to graze.

As might be expected, grass fed cattle are also nutritionally superior than even their organic grain fed counterparts. They have one-third fewer calories than grain fed beef, and substantially greater amounts of many vitamins. Furthermore, the risk of bacterial contamination is very low in grass fed cattle. Numerous recent outbreaks of *E. coli* infections in meat were from cattle that were given grain, not grass. Grain causes an abnormal, and unfavorable, high acid pH in the first stomach. Because cattle don’t digest starch well, some undigested grain reaches the colon, where it ferments. This allows various acids to accumulate in the colon, and promotes populations of acid-resistant *E. coli*. A grass diet does not disturb the normal pH of the first stomach.

Make sure that your grass fed animal is not “finished” with grain. Just one day of consuming grain in a feedlot ruins the benefits of the animal’s grass diet.

Vegetarian Fed or Grain Fed

These phrases refer to chickens and turkeys, cattle, and (less often) lambs. The phrases became widely used after the heavily publicized outbreak of so-called Mad Cow Disease, a condition augmented or caused by feeding animals the waste products and diseased flesh of other slaughtered animals.

Vegetarian fed and *grain fed* presumably lessen consumer fears of contracting the disease. However, problems arise when animals are fed grains—both for the animals, and the humans who eat them. Unless the grains are certified organic, they are at best loaded with pesticides, and at worst genetically engineered (and loaded with even more pesticides). Another problem is that cattle, bison, goats and sheep are designed to eat fibrous grasses, not starchy low-fiber grain. When ruminant animals are grain fed rather than pasture fed, the naturally (desirable) acidic pH of their first stomach is disrupted and becomes too acidic. This makes them more prone to *E. coli* infections and other diseases. Grain fed mammals also have much lower levels of many vitamins than animals allowed to eat grass.

Finally, grain fed mammals develop an abnormal amount of fat—and along with the extra weight, an unbalanced ratio of the different types of Omega fats in their bodies (discussed in a moment). Cattle, sheep, buffalo, goats and other animals are not evolutionarily designed to eat grain. Grain disrupts the animals’ metabolism, as well as the metabolism of the humans who eat them. Insulin production abnormally escalates, which in turn raises the overall fat content in the animals. Every cattle rancher knows that *grain puts weight on the animals*. The heaviest animals bring the most money, so cattle fed mostly on hay (for convenience) are fattened up on grain for a few days or weeks just before they’re slaughtered.

The increase in fat is more than cosmetic. In animals fed grain for any period, the thick white fat marbled throughout the flesh contains an approximate 30:1 ratio of Omega 6 to Omega 3 fats. (There are different types of fats, which perform different functions. Among other features, Omega 3 fatty acids are anti-inflammatory.) The typical American diet contains from 10 to 30 times more Omega 6 fatty acids than Omega 3. But a healthy diet should consist of no more than 3:1 of Omega 6s to Omega 3s—or even equal amounts of each. Because Omega 3 fatty acids cannot be made by the body and must be obtained from food, this imbalance may contribute to the rising rate of inflammatory disorders in the United States. When we eat these animals, we eat what they ate. And we are affected just as if we had been fed grain. I will say much more about grain later in this chapter.

Chickens, turkeys, ducks and birds in general do require starchy grains and seeds in their diet. However, they are also

Beware of Foods Imported from China

Even if they're labeled organic, foods from China are usually loaded with toxic metals. This is due to decades of waste run-off from excessive mining and industry. One-fifth of China's arable land—and quite a lot of its water—are polluted with arsenic, cadmium, lead, mercury, and nickel. Heavy metals are poisonous. They cause unlimited problems with digestion, the brain and nerves, the liver, and the kidneys. The metals build up in the body and can be difficult (although not impossible) to remove. In China, the manure that's allowed to be used on organic produce often contains high levels of toxic metals as well. So, organic produce from that country can actually contain more heavy metals than food that's conventionally grown almost anywhere else.

Usually, the food label will read "China." But sometimes, you'll see "PROC." Don't be fooled. This acronym stands for "People's Republic of China."

designed to live outdoors so they can scratch and peck for grubs and insects that live on or in the ground. Inherently, chickens and other birds are not vegetarians. They need the additional protein that bugs provide. So, when a label proclaims that your chicken was fed an all-grain diet, be aware that this isn't its natural diet—and that because your bird has gained extra fat due to this diet, you might too. Genuinely free range chickens and other birds that are given access to open pasture, and are allowed to eat bugs and unsprayed fruit and vegetable scraps, have a much more nutrient-rich diet. You will too, if you eat such birds.

Pastured

Not to be confused with "pasteurized," *pastured* refers to birds that live in a portable enclosure that shelters them from the elements. The structure is moved once or twice daily to a new piece of pasture so the birds can forage for insects (which comprise 20% of their diet). Birds raised this way are much happier and tastier than free range. They are also much harder to find.

Animal-Compassionate or Humanely Raised

This relatively new term, which is not legally binding, is used to persuade consumers that the animals that provide their meals are being treated humanely. But what the consumer assumes, and how the animal raisers actually treat the animals, may be two different things. Personally, I think that the only compassionate way to raise animals is to give them sunlight, company of their herd or flock, ample space to exercise, the opportunity to forage, and (if necessary) supplemental food similar to what they would eat if allowed to forage for themselves.

Sustainable

This term, which is not legally binding, is now being used to reassure the consumer that the animals are raised in such a way that minimizes large accumulations of waste and has the least amount of negative environmental impact. But what the consumer assumes, and how the animal raisers actually treat the animals and the land, may be quite different. Optimal sustainability involves moving the animals around to graze and forage naturally; allowing the animals to fertilize the land with their manure, but at amounts that the land can process; avoiding chemical pesticides and fertilizers; and administering drugs to the animals only when absolutely necessary. If these guidelines are respected, respect for the animals will automatically follow. Many people with small farms are growing crops and raising animals sustainably, but lack organic certification because they can't afford the thousands of dollars necessary to meet the legal labeling requirements.

Another aspect of *sustainable* is the freshness of the product when picked or packed. This relates to the distance it must travel to reach the consumer. Sometimes, even if an item is not certified organic, the fact that it's locally grown—and therefore has not been shipped cross-country for thousands of miles in a refrigerated truck—gives it more nutritional value.

As it turns out, the most sustainable crops are those grown without pesticides or herbicides; and the most sustainable food animals are raised on their natural diets. Cattle are grass fed, chickens run around the outdoors and eat both plants and insects, and other animals are raised in their normal environment. The best way to obtain a diet that sustains life (yours!) is to know a trustworthy farmer.

High Brix

Although *Brix* (pronounced "bricks") is unknown to even most organic farmers, this unique method of growing and evaluating crops is superior to all other methods.

The practice was begun by 19th century German chemist A.F.W. Brix, who measured the percentage of solids in a few drops of freshly squeezed juice or sap from a live fruit, root, stem or leaf. The solids measured include not only fructose, sucrose and other sugars, but also flavonoids, amino acids, minerals, oils, and more.

The device used for modern measurement is called a *refractometer*. "When the drops fall on the prism," explains contemporary farmer Rex Harrill,

you close the cover plate to spread it out, and then look through the viewing end of the instrument, where you will see an etched scale generally calibrated in 0–30 degrees or 0–32 degrees Brix. Just as a pencil appears bent when placed in a

beaker of water, the light passing through the plant juice droplet is bent so that a clear line is shown against the scaled background. The amount of bending is directly related to the richness of the plant juice (richer juice bends the light more).⁶⁴

There is a direct and intimate connection between higher Brix numbers, high life force, concentrated nutritional value, and superior flavor. Not surprisingly, these qualities indicate a rich mineral content in the soil. A Brix measurement considered excellent begins at 12 to 14, although measurements as high as 28 Brix have been recorded. Harrill says:

To me, Brix is a measure of energy. A high-Brix plant emits a far superior energetic electromagnetic spectrum than a low-Brix specimen. Insects “see” in this range and they “attack” plants with the weakest emanations. . . . All that talk about how healthy plants “resist” insects is really another way of saying that *the strongest plants don’t attract insects in the first place*. . . . A refractometer is merely a way for us to see by proxy what insects see with their eyes. [emphasis added]⁶⁵

High Brix plants are vibrant in color, have wonderful flavor (and are naturally sweet), contain abundant nutrients, and are resistant to insects, weeds and disease. They’re also resistant to rotting: Brix experts state that high Brix plants may dehydrate in storage, but will not rot. Low Brix plants are more muted in color, have bland flavor (or are sour or bitter), are nutrient depleted, and are susceptible to insects, weeds and disease. This includes rotting. (A plant with slime or mold on its surface is also rotten on the inside, even if you can’t see the rot; so it’s best not to eat the fruit or vegetable at all.)

The enhanced mineral content of high Brix plants makes the fruits and vegetables structurally different as well. For instance, a healthy orange, lemon or grapefruit has a thinner rind. Comparing two bushels of grain that have identical volume but different weights, the heavier one has more nutrients and higher Brix readings. Nutrient-dense, high Brix vegetables have a natural waxy coating on them (not the synthetic paraffin that some growers add after the produce is picked). Low Brix peaches and plums have a split pit. Low Brix vegetables are somewhat dry and hollow inside (probably indicating a boron deficiency). Potatoes with sunken eyes may be deficient in manganese.

To grow high Brix crops, the soil must be healthy. Brix readings improve when the pH of the soil is balanced. The ideal pH for almost all crops is 6.4, which requires a proper mineral ratio. There are many ways to improve the soil: most often, with high-calcium lime, and other

beneficial natural soil foods including powdered fish, seaweed, and additional sources of phosphorus, nitrogen and potassium. Friendly soil bacteria are also needed. The plants rely on bacteria to break down the rock, which allows the minerals to be utilized.

An estimated 90% to 95% of produce obtained from ordinary commercial channels is fairly low Brix. Although growing high Brix crops requires more effort and care, and perhaps a greater initial financial investment, the returns are immense. You eat less because the food is so nutrient-dense. Better nutrition means that you will be healthier. And being healthier means saving money on doctor visits, not to mention having a better earning potential. You’ll also buy fewer nutritional supplements, because the foods you eat will provide the necessary nutrition.

High Brix affects both the plants and the humans and animals that eat them. Studies show that cows eating high Brix grass and hay consume half of what they’d normally consume. They also produce more milk, which is yellow in color (probably due to a higher beta-carotene content).

If you garden or farm organically, you’re already familiar with the importance of not using pesticides. Nourishing the soil for optimal nutrition seems like the logical next step. Sources of refractometers and information on Brix are not common, so you’ll have to do an online search (also see Appendix A).

Obtaining a high Brix measurement in plants can be compared to obtaining a clean live blood analysis in a human. A healthy live blood reading shows perfectly formed, round red blood cells that are separate and distinct; viable functioning white blood cells; and no waste material in the plasma. People who get the nutrients they need have a better chance of remaining healthy. If you give a plant the nutrition *it* needs, it will remain vital. Sick humans attract pathogens. Sick plants attract insects. Whether you’re attracting harmful microorganisms or insects, both indicate a similar deficiency. They’re the human and plant equivalents of being malnourished and ill.

High Brix plants are organic even if they lack a legal certification. A plant cannot be high Brix if it’s loaded with pesticides, herbicides, and synthetic fertilizers. Ideally, all crops should be picked at the peak of their ripeness; and Brix crops would maintain their freshness longer. (They might also be locally grown.) As mentioned earlier, the US government and agribusinesses are trying hard to undermine the standards by which a plant or animal is legally allowed to be certified organic. However, establishing a separate, non-governmental network of Brix farmers may be the answer to various efforts to undermine the organic certification.

Brix holds great promise as the new way to determine crop health—and by extension, human health as well.

Carbon Monoxide, Glue, and Now ... More Bacteria in Our Meat

Supermarkets that sell meat face two major problems: keeping it fresh (as meat easily grows bacteria), and preventing it from turning brown (meat normally turns brown from exposure to oxygen before it spoils from bacteria). It's bad enough that stores must throw away bacteria-filled meat that has passed the expiration date, but they must also throw away billions of dollars worth of meat that has become discolored but is still presumably fresh.

The solution? Gas and glue. FDA-approved carbon monoxide gas is pumped into meat packages to preserve the bright pink color, which now lasts for several weeks. Industry claims that the gas is harmless at the levels used. However, consumers are worried because old product that has spoiled still *looks* fresh, even if the meat's riddled with bacteria. In response, industry lawyers have reassured consumers that they'll be able to tell if meat has spoiled if the package bulges, has an odor, and has formed slime. (Somehow, consumers are not reassured.)

If carbon monoxide-filled meat doesn't have to be labeled, how can you tell if your meat has been gassed? Examine the packaging. Normally, the plastic wrap used for packaging is thin, and clings to the meat. But when carbon monoxide is used, a thicker plastic is required to keep the gas from escaping. The wrap won't cling because the gas has to circulate over the surface of the meat in order to do its job.

But wait . . . You must also make sure that your meat doesn't contain glue. Trimmed scraps, older meat, and inferior cuts that nobody wants can be saved if they're glued together. The glue used on meat is a powder called *transglutaminase*, produced by fermenting certain strains of bacteria. The glue is mixed into the meat, water is added, the mass is shaped and sealed in a vacuum bag under pressure, and presto! The meat waste has just been transformed into a nicely-shaped piece that looks like a fancy (and expensive) filet mignon. The bond between the meat scraps is permanent and nearly invisible.

The FDA lists transglutaminase as GRAS, or "Generally Recognized As Safe." The problem is, just as with the cosmetic carbon monoxide treatment, gluing meat can promote huge levels of bacteria. Cooking a piece of real meat kills the bacteria that normally accumulate on the outside, and the inside is fairly safe. But glued meat contains a lot of "outside" pieces that had been exposed to air and thus grew bacteria. Cooking a rare or medium rare pretend "steak" will kill the outside bacteria, but the inside bacteria will not be cooked; they'll remain intact.

The solution? Buy grass fed, from a trusted source.

Staples

At some point in their lives, our great-grandparents or grandparents who subsisted on a limited income may have grappled with the problem, "What is there to eat?" Their children (our grandparents or parents), who became more affluent, had the luxury of musing, "What shall I eat?" Today, with the worldwide rise in obesity and (legitimate) escalating concerns about food safety, many of us are wondering, "What *can* I eat?"

It's assumed that the foods discussed below will be the cleanest possible. If they might be adulterated in some way, I'll explain how, so you can decide if you want to eat them or avoid them. Obviously, I am unable to list all foods grown or raised everywhere. I speak from my own perspective, based on what is available in North America.

Red Meat

This category includes all mammal meats: the more domesticated animals including cattle, lamb, goats and pigs; game animals such as bear, boar, buffalo, deer and elk; leaner, less common meat such as ostrich; and beefalo, a cross between a cow and buffalo (obtained through ordinary animal breeding techniques).

North Americans are used to eating beef, but lamb is an excellent alternative, as these animals are naturally grass fed. Goat is similarly safe, although it's often hard to find.

There's some debate about the wisdom of eating meat from pigs, especially as some researchers have easily grown the cancer virus on pig meat. This may be the origin of the prohibition against eating pig in some religions such as Judaism and Islam. Pork especially should be cooked at temperatures high enough to kill *Trichinella spiralis*, a roundworm that causes all sorts of symptoms due to its ability to burrow into the gastrointestinal and respiratory tracts, muscles (including the heart), and nerves. To avoid contracting trichinosis, cook the meat thoroughly to temperatures of at least 160°F (Fahrenheit), which is 71.1°C (Celsius). Freezing at temperatures below 21°F (minus 6.1°C) for about a week kills the larvae.

Canned meat retains much of its food value, but cans are problematic because they can outgas toxic metal particles. Also, it's hard to find canned meat products that don't contain chemicals.

Poultry

This includes chicken, duck, turkey, goose, Cornish hen, quail, squab (young pigeon), and pheasant.

A grain diet can adversely affect an animal in similar ways that it affects humans: by raising the animal's insulin production and thus raising its overall (non-beneficial) fat content. Organically raised chickens are confined

indoors more than their outdoor, free range counterparts. Outdoor birds cannot legally be certified organic because their feed can't be controlled (they scratch for their food and eat insects). However, they have a more natural diet than organically raised chickens. And they taste better.

Eggs

Eggs are among the best protein sources, with a very balanced profile of amino acids (the building blocks of protein). Eggs do contain cholesterol, but their negative publicity is undeserved. The lecithin in the egg yolk helps the body digest the cholesterol (which is also in the yolk)—and anyway, most cholesterol is produced by the body and is unrelated to dietary intake. Eggs do not cause cholesterol to form in the arteries. Studies that presumably proved this were financed by the cereal companies, and used *powdered* (fake) eggs. Unfortunately, once those studies were conducted, the myth that eggs are harmful has remained somewhat fixed in the public's consciousness. It's always worthwhile to find out who conducts and finances studies before believing the results.

The best eggs to get are direct from the farmer; if not farm-fresh, then organic. Store eggs labeled "high in Omega 3 fats" may not be as beneficial as the labels suggest, as the hens are fed poor-quality, oxidized sources of Omega 3 fats, and their eggs may spoil quickly.

If you're lucky to find someone who will sell eggs fresh from the hen, it's best if the eggs aren't washed, even if they have dirt and debris on the outside. Eggshells are naturally coated with a protective antibacterial film that dissolves once the egg is washed. Commercial eggs are dipped in a bath of chlorine, so it's best to avoid them if possible. A truly fresh, unwashed egg actually keeps better—outside the refrigerator! That is why, in Europe, it's against the law to wash eggs, and people never have to refrigerate them. If an egg is fresh, when you roll it across a table at room temperature it will be wobbly while it moves.

On his natural health website, Dr. Joseph Mercola advises not to eat an egg if the white is watery instead of gel-like, if the yolk is not firm, or if the shell is cracked or porous. Immersing the egg in salted water will elicit bubbles if the shell is damaged. He also advises:

Be aware that controlled diets of only raw egg whites can lead to severe biotin deficiency. When you consume raw egg white alone, without the yolk, a component in them called avidin binds to the B vitamin biotin, potentially creating a deficiency in your body. . . . Egg protein is easily damaged on a molecular level, even by mixing/blending. If you choose not to eat your eggs raw, cooking them soft-boiled would be your next

best option. Scrambling your eggs is one of the worst ways to eat eggs as it actually oxidizes the cholesterol in the egg yolk. If you have high cholesterol this may actually be a problem for you as the oxidized cholesterol may cause some damage in your body. . . . Heating the egg protein actually changes its chemical shape, and the distortion can easily lead to allergies. If you consume your eggs in their raw state, the incidence of egg allergy virtually disappears.⁶⁶

Another reason that many people are allergic to eggs is that pathogens for vaccines are often grown on egg cultures. Egg allergies were rare until people started being inoculated. Also, chicken eggs are used to prepare vaccines. Duck or even emu eggs may not be problematic.

If you boil your eggs, don't overcook the yolks. The greenish ring around the yolk in hard boiled eggs indicates that the yolk proteins have degraded from being heated too long. Cover the eggs with water. Bring the water to a boil and remove the eggs from the heat. Let them sit, covered, for 10 to 13 minutes depending on the size of the egg. This will keep the yolks intact. Plunge the eggs into cold water afterward to remove the shell more easily.

Fish and Seafood

There is an amazing variety of fresh and salt water finned fish and shellfish. However, due to over-fishing, some species are becoming scarce. Fish are especially valued for their oils, a perfect food for the brain and nervous system, heart, and kidneys. Oils chemist Udo Erasmus states, "The warmer the water is that the fish swims in, the lower the oil content. So, Atlantic herring cooled by the Arctic current have 11.3% oils, while Pacific herring warmed by the Japanese current have only 2.6% oils."⁶⁷

If our planet were uncontaminated, all types of fish would be safe to eat. However, toxins are commonly stored in the fatty tissues of both humans and animals. Pregnant women who eat contaminated fish pass the toxins through the placental barrier directly to the baby. Fatty deep-water fish, such as swordfish and most tuna, are caught in polluted waters that contain high levels of mercury. Farmed salmon contains high levels of persistent organic pollutants (POPs), as well as carcinogenic polychlorinated biphenyl (PCB) at levels eight times higher than in wild salmon.

We must be careful about what fish we eat, and how much. One safety guideline is to eat smaller fish. Not only do they have shorter lives, but being lower on the food chain, they eat plants and smaller animals that contain fewer contaminants. The specific guidelines below are from Environmental Defense, a 40-year-old organization devoted to solving urgent environmental problems.

- ◆ *Safest.* Fish that can safely be eaten more than once a week are anchovies, Atlantic butterfish, Atlantic herring, oysters (farmed), mackerel, Alaskan sablefish (black cod), *wild* Atlantic salmon, canned pink or sockeye salmon, sardines, and squid. The following are noted by other sources as provisionally safe (young children may eat these fish no more than once a week): black sea bass, haddock, hake, Pacific cod, yellowtail flounder, Pacific whiting, shad, and sole.
- ◆ *Reasonably Safe.* Abalone, striped bass, Arctic char, bay scallops, catfish, caviar, clams, blue mussels (farmed *and* wild), sturgeon, and shrimp from the US. Also crab (Dungeness, snow from Canada, and stone), crawfish, Pacific halibut, lobster, Atlantic mahi-mahi, shrimp from Canada, spot prawns, and tilapia.
- ◆ *Somewhat Safe.* Atlantic cod, Atlantic halibut, monkfish, skate, snapper, and tilefish.
- ◆ *Unsafe.* Grouper, marlin, orange roughy, Pacific rockfish (rock cod), farmed Atlantic salmon, Chilean sea bass (toothfish), shark, wild sturgeon, swordfish, and bluefin tuna.

Canned fish retains much of its food value. However, it often contains preservatives and texturized vegetable protein (TVP). In the body, TVP breaks down into poisonous glutamic acid, the so-called “active” ingredient in monosodium glutamate (MSG), discussed in detail shortly.

Dairy

This includes milk from cows, sheep, goats, buffalo, camels, mares, and other mammals. It also includes the butter, whey, cream, cheese, buttermilk, yogurt, quark, and other products made from their milk.

In Chapter 1, the damage to both cows and humans from recombinant Bovine Growth Hormone (rBGH) was explained in detail. As of this writing, the use of rBGH and Bovine Somatotropin (BST) has been banned in Canada, Japan and Australia, and by all 25 countries of the European Union. In the United States, some dairies refuse to use this synthetic hormone. The best way to avoid it is to either buy domestic products specifically labeled organic or BGH-free, or European cheeses, which never contain these hormones.

There’s another important feature of dairy products: raw versus pasteurized and homogenized. You are receiving only a fraction of what dairy foods have to offer if you’re not eating dairy raw, and from grass fed animals. In fact, you’re harming yourself *unless* you eat raw dairy. The pasteurization and homogenization processes damage milk in different ways. I’ll discuss pasteurization first.

Pasteurization involves heating the milk at a temperature of 145°F to 150°F (62.8°C to 65.6°C), and then cooling the milk to at least 55°F (12.8°C). The milk remains hot from 15 to 30 minutes. With “ultra-high temperature” pasteurization (UHT), temperatures are raised to 280°F (137.8°C) for at least two seconds. This supposedly extends the shelf life of refrigerated milk for six months.

All pasteurized milk is adulterated and dead; I would not use the word “food” to describe this fabrication. The stated purpose of pasteurization is to destroy germs that carry disease and to prevent milk from souring. But these goals aren’t achieved, as pasteurization kills beneficial as well as harmful bacteria. Normally, if raw milk is allowed to sit, the beneficial lactic acid bacteria will (desirably) sour the fluid, which makes the milk highly assimilable and even healing to the digestive tract. The fear that raw milk easily spoils contradicts the historical use of raw milk to preserve meat. For centuries, Arabs preserved meat in raw camel milk. People from Iceland preserved sheep’s heads in soured raw milk. In the United States, pioneers preserved meat in raw buttermilk and enjoyed meat all year round. The truth is, *it’s the heating that allows the milk to spoil, and to spoil more quickly*, because it escalates bacterial growth exponentially. The milk gradually turns rancid in a few days, and then decomposes. When raw milk is left alone at moderate temperatures, it simply ferments into a healthful, cultured product.

Note that pasteurization doesn’t remove dirt, and it doesn’t eliminate or immobilize the wastes that the bacteria produce. Thus, even organic pasteurized and homogenized milk can cause problems because it contains toxins along with the remains of the dead bacteria killed by pasteurization. Symptoms include indigestion, respiratory distress, excessive production of mucus, fatigue, brain fog, and muscle and joint pain.

Misinformation about raw milk being full of germs has been widely disseminated. Before the advent of high-tech pasteurization methods that ruined good milk, raw dairy was used as a tonic for hard-to-treat illnesses. Dr. Ron Schmid’s “Real Milk” website contains lots of interesting data. It also features excerpts from an article by a Dr. J. Crewe of the Mayo Foundation (forerunner of the famous Mayo Clinic in the US). The article—which was originally published in the January 1929 issue of *Certified Milk Magazine*⁶⁸ and quoted from the eighth edition of the medical text *Principles and Practices of Medicine*—summarized the therapeutic use of raw, butterfat-rich milk from pasture fed cows. Many diverse conditions were successfully treated with such milk, including hypertension and other cardiovascular conditions; nervous system ailments; nephritis and other

kidney problems; psoriasis; and tuberculosis. A Dr. Crewe presented his findings to the Minnesota State Medical Society in 1923. At that point, he had been successfully treating people with raw milk for 15 years. More current sources, including physician William Campbell Douglass and the Weston A. Price Foundation, cite the use of raw milk (and raw whey) in eradicating many diseases, including asthma, stomach ulcers and diabetes.

The high heat of pasteurization also destroys almost all of the crucial vitamins, minerals, enzymes, and other nutrients that make raw milk so healthy. In fact, the gauge of pasteurization's success is based on the destruction of enzymes! (See Insert on pages 302–305, “Comparison Chart between Raw and Pasteurized Milk,” to see what's destroyed as well as the effects of the destruction.)

For decades, the cattle dairy industry has called milk the perfect food due to its substantial calcium content. This may be the most popular selling point of milk, but ironically the heat of pasteurization makes most of the calcium unable to be dissolved, and hence unusable by the body. Not only is a calcium deficiency created—which can lead to soft, improperly formed bones and teeth—but the insoluble form of calcium can cause constipation and the formation of calcium deposits (stones) in the body.

Now let's discuss homogenization, which also damages milk. The milk is pumped at high pressure through a small opening to disperse the heavy, creamy fat molecules throughout the fluid. This makes the fat molecules smaller, and of uniform size and consistency. (Otherwise, the cream would rise to the top.) This process is not benign. Fats expert Mary G. Enig, PhD, writes:

There is a tremendous increase in surface area on the fat globules. The original fat globule membrane is lost and a new one is formed that incorporates a much greater portion of casein and whey proteins. This may account for the increased allergenicity of modern processed milk.⁶⁹

Detractors of raw milk associate it with unclean conditions. However, cows raised for raw milk are much more heavily inspected than cows raised on factory farm dairies. Raw dairy farmers must keep the cows, their living quarters, and the milking equipment scrupulously clean. Several people employed by commercial (non-raw) dairies have told me that they saw batches of processed milk with “unacceptable” levels of contamination made “acceptable” again because cleaner batches were added to the contaminated ones—thus bringing the total contamination levels within the range allowed by law.

The FDA works hard to prevent people from having access to raw milk. Some farmers in states that prohibit

raw milk sell cow shares. The shareholders visit the farm daily or weekly to fill their own containers with fresh milk. In response, FDA agents have trespassed onto several of these farms and confiscated the milk, even though the shareholder program is legal. One must ask, “Whose interests does the FDA really represent?”

Even though raw milk has been a beneficial staple in the diet of millions of people for centuries, not everyone can metabolize it. There are several possible reasons for this. First, people of Asian, Eastern European, Native American, and (in some instances) African ancestry lack the enzymes to digest cow dairy—probably because their forebears did not eat dairy as part of their traditional diet, and therefore never developed the requisite enzymes. In these cases, even the enzymes already present in raw milk are not adequate to help overcome milk intolerance.

People who negatively react to *lactose*, or milk sugar, can take a *lactase* enzyme supplement, which digests milk sugar. If the body's bile stores are depleted, fat-digesting enzymes can be taken. However, even supplementation may not be enough to restore tolerance. We know this thanks to recent research on proteins in milk.

Beta-caseins, the second most abundant proteins in cow's milk, are divided into two groups called *A1* and *A2*. Each has a different amino acid located at position 67 on the protein chain: *A1* contains histidine and *A2* contains proline. When the body breaks down the *A1* beta-casein, it creates an irritating fragment called *beta-casomorphin7* or BCM7, which is an opiate and oxidant. High levels of BCM7 are present in the blood of people with autism, schizophrenia, and possibly diabetes and heart disease. In contrast, *A2* doesn't irritate. It's the sole protein in goat, sheep, camel, yak, and human milks. It was also the sole protein in cow's milk until a mutation occurred in the bloodline of European cattle centuries ago. *A1* proteins are present in the milk of the majority of cows from Western countries, while *A2* proteins are in the milk of cows living in Asia, Africa, and portions of Southern Europe. Today, most dairies raise *A1* Holsteins, which are black and white. However, milk from most Jersey and Guernsey cows, and probably all Normande cows, is *A2*. Interestingly, it appears that all *A2* cows are brown. Some *A2* animals are now being bred in New Zealand, the US, and Australia. The only sure way to determine which proteins are in dairy is to conduct a DNA test on the cow.

People negatively affected by *A1* milk might be able to handle *A2* milk. Camel's milk has the reputation of containing beneficial anti-inflammatory compounds. As a general rule, milk from smaller animals is more easily assimilated by humans because the fat molecules are on a smaller (human) scale. Also, the nutrient proportions in

Comparison Chart Between Raw and Pasteurized Milk (from Grass Fed Cows)

Note: Feeding the cows exclusively grass, rather than grain, is as important as drinking the milk raw.

Nutrient	Role in Nutrition	Raw Milk	Pasteurized Milk
Proteins (general)	Amino acids comprise 75% of the body's dry weight, all but one neurotransmitter, 95% of hormones, and 100% of all protein. They govern and participate in every chemical reaction in the body.	All 22 amino acids are 100% available, including the eight essential amino acids.	The amino acids lysine and tyrosine are altered by heat with serious loss of metabolic availability. This results in making the whole protein complex less available for tissue repair and rebuilding. Disease indicates an abnormality of amino acid structure and function.
Caseins and Whey Proteins	Caseins comprise about 80% of the proteins in milk. They are reasonably heat stable and easy to digest. The remaining 20% of milk proteins are whey proteins. These are also easy to digest, but they are also very heat sensitive. Among the whey proteins are key enzymes, immunoglobulins (antibodies), metal-binding proteins, vitamin binding proteins, and growth factors. See below for a few specifics.	Available.	Caseins are mostly intact, but the co-factors needed to help digest them are not, making heat-treated milk difficult to digest. Most of the whey proteins are destroyed.
Immuno-globulins	This complex class of milk proteins called antibodies, which are inherently present in raw milk, render it less vulnerable to bacterial contamination. They also confer resistance to many viruses, bacteria, fungi and bacterial toxins.	All are available.	Nearly all are destroyed.
Nisin	A natural antimicrobial agent rich in amino acids, it is a natural antimicrobial agent used worldwide. Has been used since 1953 to control bacterial overgrowth in foods. It is produced by <i>Lactococcus lactis</i> , a beneficial bacterium naturally present in raw milk.	Available.	Destroyed. Pasteurization kills beneficial as well as harmful bacteria.
Lactoferrin	A protein, whose unique ability to bind to iron helps improve absorption and assimilation of iron. It also has antifungal, antibacterial, antiviral and anti-cancer capabilities because it deprives tumors and pathogens of iron, which they utilize for growth and reproduction. Stimulates immune cells to engulf pathogens and foreign materials. Also is a powerful antioxidant and anti-inflammatory agent.	Available.	When milk is pasteurized at the lowest possible heat, the lactoferrin appears to be intact. However, very high pasteurization temperatures (305°F or 151.7 °C), combined with high pressure homogenization, some or all of the lactoferrin is completely inactivated.

Nutrient	Role in Nutrition	Raw Milk	Pasteurized Milk
Enzymes (general)	A class of biochemicals, made from small chains of amino acids, that catalyze all metabolic and life processes without being used up in the process. Enzymes assist with everything from cellular growth to protection against infection.	All are available. There are over 60 known enzymes in raw milk.	Essentially destroyed. Pasteurization is in fact defined as succeeding according to the absence of enzymes. Among other disadvantages, the loss of enzymes prevents the assimilation of minerals.
Lacto-peroxidase	The second most abundant enzyme in milk. A strong antimicrobial agent in milk, saliva and tears. Inhibits the growth of <i>Salmonella</i> and other bacteria, yeasts, fungi, and viruses.	Found almost exclusively in the whey after cheese making; carbohydrate content about 10%.	Fairly unavailable after being heated.
Lysozyme	Enzyme. Can break apart cell walls of certain undesirable bacteria.	Available.	Reports are mixed. Sources either report destruction of this enzyme, or say that it appears to remain fairly intact.
Catalase	Enzyme. Helps prevent unwanted bacterial contamination.	Available.	Largely destroyed.
Lipase	Enzyme that helps digest fats.	Completely available.	Completely destroyed.
Lactase	Enzyme that helps digest lactose (milk sugar), the principal carbohydrate in milk.	Completely available.	Completely destroyed (some milk companies add it to the milk after processing). For almost half of the world's population whose digestive systems are completely or partially deficient in lactase (and who are said to be "lactose intolerant"), drinking pasteurized milk can cause diarrhea, bloating and cramping.
IgG, a.k.a. Enzyme Immuno-globulin G	Enzyme that inhibits rotaviruses that cause diarrhea in infants.	Completely available.	Partially destroyed. Johns Hopkins University discovered that raw milk contains 250% more of this enzyme than pasteurized milk.
Phosphatase	Enzyme essential for calcium absorption.	Completely available, and plentiful.	Completely destroyed.

Fats	Help metabolize protein and calcium, construction materials of cell membranes and hormones, chief foods of the nervous system and heart, provide energy storage and protection for organs, act as vehicles for fat-soluble vitamins. All natural protein-bearing foods contain fats. Fats cause the stomach to secrete the hormone CCK, which—aside from helping the body secrete digestive enzymes—sends a message to the brain when the stomach is full. The absence of fats in non-fat dairy products (as well as other fat-free foods) helps contribute to over-eating.	All 18 fatty acids metabolically available, both saturated and unsaturated fats. Fatty acid profile of Omega 6 fats to Omega 3 fats is pretty much a perfect 1:1 in grass fed cows.	Destroyed, including the 10 essential unsaturated fats. Fatty acid profile of Omega 6 fats to Omega 3 fats is almost 5.7:1 in grass fed cows. This means that there are almost six times more Omega 6 fats than there are Omega 3 fats, which is a very unhealthy ratio. Too many Omega 6 fats means more cardiovascular and metabolic diseases.
Conjugated Linoleic Acid (CLA)	Polyunsaturated Omega 6 fatty acid that raises metabolic rate, helps remove abdominal fat, boosts muscle growth, reduces resistance to insulin, strengthens immunity, and lowers food allergy reactions.	Available.	Mostly destroyed.
Vitamins, water-soluble	Help with tissue repair and maintenance on all levels. Number of functions is too long to list.	All are 100% available.	Water-soluble vitamins are affected by heat and losses can range from 38% to 80%. Vitamin C loss by itself usually exceeds 50%. At least one quarter of all B Vitamins are lost.
Vitamins, fat-soluble	Help with tissue repair and maintenance on all levels. Number of functions is too long to list.	All are 100% available.	Among the fat-soluble vitamins, some are classed as unstable and therefore a loss is caused by heating above blood temperature. The loss of Vitamins A, D, E and F can run as high as 66%.
Vitamin B12	One of many water-soluble vitamins. Mentioned separately because it is abundant in raw milk, and very difficult to find in vegetarian sources.	This vitamin is 100% available.	Largely destroyed.
Lactose (carbo-hydrate)	Lactose is the naturally-occurring sugar in milk.	Easily utilized during metabolism.	Pasteurization turns the lactose into beta-lactose, which is absorbed more quickly by the body and thus floods the system with too much glucose at once. May be the origin of higher than normal incidences of diabetes and hypoglycemia in those who drink pasteurized milk.
Minerals (general)	Major minerals include calcium, magnesium, phosphorus, potassium, sodium, sulfur and chlorine (the beneficial trace mineral, not the toxic chemical). There are at least 24 vital trace minerals.	All major minerals are 100% available. The trace minerals are also 100% available.	There are losses in other essential minerals, as one mineral usually acts synergistically with another element. Also, the loss of enzymes prevents the assimilation of minerals.

Nutrient	Role in Nutrition	Raw Milk	Pasteurized Milk
Calcium	Abundant in raw milk. Most noted for building bone and teeth, increasing bone density and lowering risk of osteoporosis and fractures in older adults. Aids in muscle contraction. Also assists with electrical conduction along nerves and blood clotting. Also fights cancers, especially colon cancer.	Available. In order to be absorbed, calcium must be balanced with the proper ratio of phosphorus and magnesium. These two other minerals are also available in raw milk.	Calcium is altered by heat and loss in metabolism may run 50% or more, depending on pasteurization temperature.
Phosphorus	Builds bones and teeth. Responsible for energy production, acid-base balance, proper metabolism, cell membrane function, and calcium absorption.	Available.	Completely destroyed.
Magnesium	Abundant in raw milk. Helps build bone and teeth. Aids in necessary muscle expansion. Also responsible for transfer of bodily fluids and alkaline balance.	Available.	Less available.
Bacteria (beneficial)	Some of the beneficial bacteria strains break down the milk fats. Others transform lactose (milk sugar) into lactic acid. Lactic acid improves absorption of calcium, iron and phosphorus, breaks up casein into smaller particles, and helps destroy pathogens.	Bacteria grow very slowly, because the friendly acid-forming bacteria—nature's antiseptic—retard the growth of invading pathogens. Raw milk usually keeps for several weeks when under refrigeration, and will sour instead of rot.	Beneficial bacterial are completely destroyed. Pasteurization does not prevent unwanted pathogenic bacterial from contaminating the milk after it cools.

smaller mammals more closely resemble those of human milk. For instance, in cow's milk, its much higher ratio of phosphorus to calcium compared to human milk may actually prevent the absorption of calcium in humans who consume bovine dairy products. Note that the minerals magnesium and boron, as well as Vitamin D3, help with calcium assimilation. Raw milk contains all of the nutrients necessary to utilize calcium; adulterated milk does not. People who cannot tolerate even raw dairy can obtain calcium from leafy green vegetables.

Some dairy intolerant people might be reacting to what the animal ate, or even the bromine solution that many dairies use to wash the cow's udders (although it's unlikely that a raw dairy would use toxic bromine). Sometimes, people otherwise intolerant of dairy can handle *fermented* milk products: crème fraîche, yogurt, kefir, buttermilk, and sour cream. Through the process of fermentation, beneficial bacteria predigest the food, thus rendering it more easily absorbed. (By the way, food *intolerances* vs. food *allergies* both reveal negative reactions to food. However, an allergic response features an immediate production of immune-related *antibodies* to food that's perceived by the body as a foreign invader.)

To summarize: Pasteurization and homogenization destroy most of the enzymes, vitamins, and minerals that make milk nutritious and digestible. The nutrients in raw milk and raw whey (from grass fed cows) have helped many adults and children recover from a variety of illnesses including asthma, chronic fatigue, and recurring infections. If you can't obtain raw dairy products, avoid homogenized or ultra-pasteurized dairy products; many organic dairy farms now carry non-homogenized milk, cream, and yogurt. Some people who cannot tolerate even raw grass fed dairy from cows do tolerate dairy from fermented milk or A2 animals of all types, whose protein chains don't create toxins.

Vegetables

This broad category includes leaves, stems, the tops and roots of a plant, and in some cases even seed pods. All these different plant parts have been classified as a "vegetable," even though they might have radically different properties.

Leaves include arugula, bok choy, Brussels sprouts, cabbage, chicory, dandelion, escarole, kale, lettuce, mustard greens, spinach, and watercress.

Stems (stalks) include celery, leeks, chard, broccoli stalks, rhubarb, and scallions.

Roots (tubers) include carrots, beets, parsnips, radishes, potatoes, yams, sweet potatoes, and taro.

Sometimes we eat the unopened flowers, although we might not think of it in those terms. This includes broccoli and cauliflower, whose flowers are eaten with the stalks.

Other vegetables we call herbs: the tops of roots, such as parsley and cilantro. We also eat gourds (cucumber, okra and squash), seed covering crops (green beans and bell peppers), and crops technically classified as fruit but eaten as vegetables, such as tomatoes, avocados and lemons.

Vegetables in the *Solanaceae* family, a subset of nightshades, encompasses thousands of vines, trees, herbs, and shrubs. They include the poisonous inedible deadly nightshade (*Atropa belladonna*), which, if just rubbed on the eyelids, can cause death. Tomato, white potato, eggplant, goji berry, ground cherry, cape gooseberry, tobacco, tomatillo, and sweet and hot peppers (bell, chili, cayenne, and paprika) are also in the *Solanaceae* family.

The most well-known nightshade alkaloid is *solanine*. It takes one to two months for the body to excrete half of the solanine that's been ingested. *Solanaceae* plants also contain nicotine (*Nicotiana tabacum*). Another toxic compound is calcitriol—a different, and much more potent, form of Vitamin D than the D3 created by the body. Naturopath Garrett L. Smith reports that although some calcitriol (which maintains proper bone density) is produced by the body, too much calcitriol from *any* source causes hypercalcemia (high blood calcium). To normalize blood calcium levels, the body deposits the extra calcium in the soft tissues, which build up over time in the cartilage, heart, kidneys, ligaments, skin, and tendons.

Nightshade ingestion can exacerbate or cause muscle pain and stiffness, joint pain and cracking, insomnia, indigestion, acid reflux, nausea and vomiting, cardiac arrhythmia, neurological disorders, general inflammation, and even scleroderma (hardening of connective tissue in the entire body). Many disease conditions—osteoarthritis, gout, rheumatoid arthritis, coronary artery disease, and bone spurs—are related to nightshade poisons that accumulate in tissues and joints. In a study published in *Journal of Neurological and Orthopedic Medical Surgery*, symptoms of more than 70% of the test subjects with rheumatoid arthritis were substantially relieved when nightshade foods were eliminated from the diet.⁷⁰

People susceptible to nightshade-related conditions cannot completely detoxify nightshade compounds due to weakened liver and kidneys. Deficiencies in magnesium and Vitamins D3 and K2 also play a role. The high heat of cooking reduces nightshade alkaloids by only half (if that much); so if you eat nightshades, take extra nutritional supplements, and/or eat the nightshades with fatty grass fed meats, oily fish, butter, and/or cheese. If potatoes contain green parts, discard them; don't simply cut off the green and assume that the rest is okay. Green potatoes and potato sprouts shouldn't even be given to livestock. As for tomatoes, they can cause the most damage if they are eaten unripe, or in concentrated amounts (like sauce).

Sweet potatoes, part of the morning glory genus, belong to the immense *Solanaceae* family of plants. However, I'm unaware of nightshade-intolerant people—who are adversely affected by tomatoes, peppers and eggplant—who also react negatively to sweet potatoes. Not all *Solanaceae* plants share the same characteristics.

An entirely different class of vegetables called *goitrogens* includes members of the brassica family: arugula, bok choy, broccoli, Brussels sprouts, cabbage, cauliflower, collards, daikon and other radishes, horseradish, kale, mustard, canola or rapeseed, rutabaga, tatsoi, turnip, and watercress. Goitrogenous foods shouldn't be eaten raw by people with low thyroid function. They contain high levels of *glucosinolates*, which form compounds that interfere with the body's uptake of iodine. If the thyroid gland doesn't have enough iodine, it cannot produce thyroxine (a hormone) and won't function properly. Fortunately, you can disable the thyroid-lowering function of these vegetables through fermentation (as in turning cabbage into sauerkraut), or by cooking with high heat. According to studies, the cooking methods that decrease the glucosinolate levels are boiling, stir-frying, and steaming for longer than seven minutes. These vegetables contain many nutrients and are low in starch, so it's worth making the effort to prepare them properly.

Frozen and dried vegetables are almost as nutritious as fresh. Commercially canned produce has little nutritional value, and the cans are toxic (discussed shortly). However, home-canned produce packed in glass jars is safe.

Fruits

The many varieties include temperate-climate apples, pears, cherries, berries (blueberries, raspberries, blackberries, mulberries), figs, peaches, apricots, plums, and nectarines; and warmer-climate and tropical fruits mangoes, dates, bananas, lemons, papayas, oranges, grapefruit, and pineapples.

Despite fruit's fiber content, its high sugar levels are harmful to carbohydrate-sensitive and sick people (over half the population). Pathogens love sugar; so if you suffer from a chronic infection or degenerative illness, curtail your fruit intake until you're stronger. Also, be aware that a waxy coating is applied to many fruits to protect them during shipping; and the wax, unless specified as beeswax, is made from petroleum. Beeswax may be used more for organic fruits and vegetables, but it's inedible. Therefore, you may still want to peel the item before eating it.

Many growers pick the fruit before it's ripe (such as bananas). Then polyethylene gas is used to "ripen" the fruit after it's shipped. This is another reason to buy organic. I'll discuss fructose (fruit sugar) in detail shortly.

Legumes

The legume family includes peanuts, lentils, cashews (erroneously called "nuts"), green and yellow peas, and beans, which include adzuki, kidney, pinto, fava, white, lima, navy, and black. Most legumes (as well as grains and seeds) contain phytic acid. In the intestinal tract, phytic acid inhibits the activity of pepsin, amylase and trypsin, enzymes required to digest food. Phytic acid may also bind to proteins and especially minerals, lowering the absorption rates of calcium, magnesium, copper, iron, and zinc. The ability to break down phytic acid requires the appropriate intestinal flora, which most people lack.

Some beans contain large, complex sugars called oligosaccharides. Mammals do not produce the alpha-galactosidase enzyme, which is needed to break down these sugars. "When consumed," one writer states, "these oligosaccharides reach the lower intestine largely intact, and in the presence of anaerobic bacteria ferment and produce carbon dioxide and methane gases, as well as a good deal of discomfort, not to mention embarrassment in polite society."⁷¹ However, some of these complex sugars are valuable. Called "resistant starches," they act like fiber. They don't provide calories for the eater, but they are food for the beneficial intestinal flora that help us digest our food. Black (or turtle) beans contain more resistant starch than any other legume (26.9%), although white beans, navy beans, and peas also contain generous amounts.

Legumes (along with grains and nightshades) also contain sticky proteins called *lectins*. Lectins, which act as a natural insecticide to protect the plant, attach to the body's cells like glue—thus exacerbating, and even causing, autoimmune disorders among other conditions.

As with grains, legumes become more digestible if they are first soaked for 12 to 24 hours, and are then gently cooked for 4 to 8 hours, with an acid such as lemon juice or apple cider vinegar added to the water.

Soy is a legume that has become a staple in the diets of many vegetarians and health-conscious consumers. But to develop a market, the million-dollar soy industry has presented only partial truths, as well as outright falsified "research." See the Insert on page 308, "Soy: A Serious Non-Food." It cites websites that report how people's health has improved once soy was eliminated from their diet.

Seeds and Nuts

Seeds include pumpkin, flax, sunflower, and sesame seeds. Nuts include almonds, cashews, filberts, macadamia nuts, hazelnuts, pecans, walnuts, chestnuts, and coconuts. Most nuts and seeds contain over 50% fat. The inability to digest nuts may indicate a poorly functioning liver, which secretes bile to digest fats. (Nuts are high in fat.)

Soy: A Serious Non-Food

Soybeans are famous for their *isoflavones*, or *plant estrogens* (phytoestrogens). Due to their ability to mimic the natural estrogen in the human body, isoflavones disrupt hormonal functions by either excessively stimulating the body's estrogen receptors, or shutting them down. A May 31, 2001 press release from the National Institute of Environmental Health Sciences reported that infant mice given genistein (one of the isoflavones in soy) developed cancer of the uterus. This effect is similar to that caused by the synthetic estrogen DES, or diethylstilbestrol, which was once used to prevent miscarriage in humans (and to fatten animals). DES was taken off the market after it caused cancers in both mothers and offspring. However, soy is still used as food, despite ample scientific research showing its dangers.

Here are some more facts about soy, as reported by Kaayla T. Daniel in *The Whole Soy Story*, soy onlineservice.co.nz, and the Weston A. Price Foundation:

- ◆ Soy phytoestrogens may cause infertility and promote breast cancer in adult women.
- ◆ These same phytoestrogens cause premature sexual development in both girls and boys who eat it. Sometimes boys become so feminized that they grow breasts. (Usually the breast growth reverses once soy is withdrawn from the diet.)
- ◆ Soy contains the scientifically documented carcinogenic, DNA-damaging and chromosome-damaging natural chemicals genistein and daidzein.
- ◆ Soy phytoestrogens are potent anti-thyroid agents that cause hypothyroidism and may even cause thyroid cancer. In infants, consumption of soy formula has been linked to autoimmune thyroid disease.
- ◆ Soy contains high levels of trypsin inhibitors, which interfere with protein digestion and may cause pancreatic disorders. In test animals, soy containing trypsin inhibitors caused stunted growth.
- ◆ Soy contains high levels of phytic acid, which reduces assimilation of calcium, magnesium, copper, iron and zinc. The phytic acid cannot be neutralized by soaking, sprouting, or long slow cooking. High phytate diets have caused growth problems in children.
- ◆ Soy contains Vitamin B12 *analogs* rather than the vitamin itself. The analog latches onto cell receptor sites for B12; but because it's not the actual vitamin, it doesn't provide any of the benefits of real B12, and ultimately it creates a B12 deficiency.
- ◆ Soy foods increase the body's requirement for Vitamin D.

Soy proponents maintain that Asians have used soybeans for thousands of years. But the tiny legume originally used in Asia is quite different from its much larger, highly bred relative. Soybeans were planted mostly for animals to eat, and to put nitrogen back into the soil, because they are basically indigestible. Their high levels of enzyme inhibitors prevent the body from easily absorbing and utilizing calcium, magnesium, and zinc. When soy is processed, the high heat necessary to destroy the enzyme inhibitors also destroys some essential amino acids such as lysine. For these reasons and more, the original soy recipes from Asia *fermented the bean first*. Once fermented, the miso, soy sauce and tempeh—the only edible forms of soy—could be digested. In addition, these foods are used mostly as condiments, not as a main course or as meat substitutes.

In contrast to centuries-old, carefully fermented soy condiments, modern fake foods made from soy are unfermented and indigestible. As their labels indicate, the protein powders, imitation cheese, ice cream substitutes, meat-like cutlets, and even infant formula are made with denatured soy protein *isolate*. Any food that's an *isolate* is isolated, removed from its natural matrix. It's subjected to so much processing that it's no longer a whole food, but *fragmented*. On this basis alone, products made with soy protein isolate should be avoided. Soy protein isolate never received GRAS (Generally Recognized As Safe) status from the FDA as an edible food. It was approved, in 1959, solely as a binder for cardboard boxes.

The processing of most soy products creates:

- ◆ Denatured, fragile proteins, due to the high temperatures. (This especially pertains to the production of soy protein isolate and textured vegetable protein.)
- ◆ Toxic lysinoalanine and highly carcinogenic nitrosamines.
- ◆ Free glutamic acid or MSG, a potent neurotoxin.

Some women report feeling better when they eat soy. I personally knew two women who suffered from hormonal imbalances that eating phytoestrogens helped to correct. But I've also known many more people who have eaten soy and as a result, suffered from disrupted menstrual periods, diminished thyroid function, impaired memory, and premature aging. Vegetarians who insist on making unfermented soy a mainstay in their diet may be impairing their health and the health of their children.

Soy isn't suitable for everyday consumption. However, its ability to induce powerful hormonal changes potentially makes it a very helpful medicine if properly used. If you eat lots of soy, pay attention to how you feel and stop eating it if you don't feel well.

Opinions differ as to whether nuts should be eaten raw or roasted. For some people, raw nuts soaked overnight makes them more digestible. Sprouting liberates many valuable enzymes—after all, a sprout is the beginning of a vital, chlorophyll-rich green plant—although not all of the natural chemicals that are liberated in growing plant sprouts are beneficial for humans.

Almonds belong to the same family as apricots and plums. The seeds (kernels) inside the hard pits look and taste like bitter almond. Apricot kernels are the source of the anti-cancer drug Laetrile®—which G. Edward Griffin points out is basically Vitamin B17. The botanical relationship of almonds and apricots may explain why psychic Edgar Cayce advised in his famous nutritional readings that eating three almonds a day would prevent cancer. (Note, however, that bitter almonds, not the sweet ones, contain B17.) Almonds are also considered special because, unlike other nuts and seeds, for people of a certain metabolic type they help alkalize the system. These health benefits—and the FDA’s hostility toward natural health—may explain why the FDA passed a law requiring all almonds to be irradiated (the agency calls it “pasteurization”), thus rendering them lifeless, incapable of sprouting. Even though irradiated almonds contain no life force, they are legally allowed to be called raw.

Fats and Oils

Healthful fats have been eaten for thousands of years by native peoples adhering to traditional diets. They include animal fats, oils from coconut, olive and flaxseed (also known as linseed when used for industrial purposes), and raw butter. Animal fats and coconut oil can withstand fairly high heat. Butter and olive oil can survive moderate heat. Flax oil should be unheated, eaten fresh (as oil or as freshly ground seeds), and refrigerated.

Americans have been taught to fear dietary fat, evidenced by a glut of supermarket items peddled as “low fat,” “zero fat,” and “low cholesterol.” But these no-fat foods are unnatural. The right kinds of fat—saturated and unsaturated, some from vegetables but most from animals—are an essential part of the human diet. Fats lubricate the tissues, assist with metabolism, provide essential nutrients, and satisfy hunger. Fats provide the beneficial type of cholesterol that makes bile salts, hormones, and Vitamin D. Our heart and kidneys can’t survive without fat. Our nerve cells are coated with fat, which acts as insulation—similar to the rubber that surrounds electrical wiring (which is analagous to the nerve cells). If we don’t eat enough of the proper fats, the messages conducted along the nerves become scrambled due to poor insulation. Also, fats comprise over 70% of the brain. This helps us think, concentrate, remember,

Did you know that your heart uses *fat* exclusively as its source of energy? Now why would your heart only choose fat? It cannot miss a beat and needs a very reliable and optimum source of energy. Carbohydrates and glucose are *too unreliable* for your heart. Glucose is inferior for muscle power and only your brain is truly efficient at burning glucose as its source of fuel. Your brain is unique because it has the ability to utilize glucose without insulin being present. What this tells us is that the human body is a fat burning organism that is designed to operate on *small amounts* of insulin and carbohydrate.

—Jay Robb, *The Fat Burning Diet*, 1996

move, sense, and perceive correctly. The high amounts of fat in human milk help an infant develop properly.

If animal fats are so important in the diet, why are some people afraid to eat them? In “The Oiling of America” (some of it excerpted in the page 310 Sidebar, “The Truth About Canola Oil”), biochemical researcher Dr. Mary Enig and nutrition activist Sally Fallon describe how, over five decades ago, the “edible” oils industry deliberately generated negative publicity for animal fats and coconut oil to create a lucrative market for their own highly processed, fabricated vegetable oils. Enig’s research, showing the harm of processed hydrogenated fats, was deliberately falsified. The popular fiction that animal fat is completely saturated, is misleading and wrong. Beef fat is 54% unsaturated, lard is 60% unsaturated, and chicken fat is about 70% unsaturated.

Dietary fat does not automatically translate into bodily fat. It’s an excess of carbohydrates (sugars and starches), rather than unaltered fats, that leads to overweight (discussed later in this chapter). Note, for instance, that the diet of the Inuit (Eskimos) consists of about 80% whale and seal blubber.

What about oils designated “cold pressed”? This simply means that the oils have not been heated after being extracted from their source. But even vegetable oils labeled “cold pressed” heat up considerably as a result of the intense pressure—20 tons per square inch—needed to extract the oil in the first place. Compare the pressure required to squeeze oil from a hard seed or nut, to that needed for a fleshy olive or tiny soft sesame seeds! So, even though a vegetable oil may be processed without chemical solvents, artificial preservatives or *extra* heating, as soon as the now-hot oil is squeezed out of nuts and seeds, it starts to turn rancid. One such oil is canola.

Canola, grown extensively in Canada, has until recently been known as rapeseed. To make the oil more appealing to a mass market, Canadian scientists renamed the product. (Most sources cited the name as a shortened

form of “Canadian Oil Low Acid.”) The oil was developed using manual cross-breeding techniques on two related cruciferous plants, both known as rapeseed, to lower what was regarded as excessive levels of naturally-occurring erucic acid. Further attempts to alter canola were done by bombarding the seeds with radiation, a form of genetic engineering. Over 50% of today’s canola crop is genetically engineered by Monsanto, which automatically means that you’re ingesting huge amounts of the herbicide Roundup® with your food. Even if your canola oil is organic, it’s high in *glycosides*, sugar-related compounds that inhibit enzyme function and destroy the protective coating of the nerves.

This oil is widely marketed as healthy, and appears in the majority of products found in health food stores.

The coconut’s negative reputation is undeserved. Although coconuts contain up to 60% fat (of which over 90% is saturated), these fats are essential fatty acids (EFAs)—and thus mandatory for life processes. Coconut’s unique molecular structure of medium-chain fatty acids does not cause weight gain, as long as it’s not eaten in excess. Rather, the fat is highly digestible, sates the appetite, and helps burn body fat. Old studies linking coconut oil with high cholesterol, heart attacks, and other negative conditions were based on *adulterated coconut fat*

The Truth About Canola Oil

Canola oil is definitely not healthy for the cardiovascular system. Like rapeseed oil, its predecessor, canola oil is associated with fibrotic lesions of the heart. It also causes Vitamin E deficiency, undesirable changes in the blood platelets and shortened life-span in stroke-prone rats when it was the only oil in the animals’ diet. Furthermore, it seems to retard growth, which is why the FDA does not allow the use of canola oil in infant formula.

The animal studies carried out over the past twenty years suggest that when rapeseed oil is used in impoverished human diets, without adequately saturated fats from ghee, coconut oil or lard, then the deleterious effects are magnified. In the context of healthy traditional diets that include saturated fats, rapeseed oil, and in particular the erucic acid in rapeseed oil, does not pose a problem. In fact, erucic acid is helpful in the treatment of the wasting disease adrenoleukodystrophy and was the magic ingredient in Lorenzo’s oil.

High levels of Omega 3 fatty acids, present in unprocessed rapeseed oil, don’t pose a problem either when the diet is high in saturates. Rapeseed has been used as a source of oil since ancient times because it is easily extracted from the seed. Interestingly, the seeds were first cooked before the oil is extracted. In China and India, rapeseed oil was provided by thousands of peddlers operating small stone presses that press out the oil at low temperatures. What the merchant then sells to the housewife is absolutely fresh.

Modern oil processing is a different thing entirely. The oil is removed by a combination of high temperature mechanical pressing and solvent extraction. Traces of the solvent (usually hexane) remain in the oil, even after considerable refining. Like all modern vegetable oils, canola oil goes through the process of caustic refining, bleaching and degumming—all of which involve high temperatures or chemicals of questionable safety. And because canola oil is high in Omega 3 fatty acids, which easily become rancid and foul-smelling when subjected to oxygen and high temperatures, it must be deodorized. The standard deodorization process removes a large portion of the Omega 3 fatty acids by turning them into trans fatty acids. Although the Canadian government lists the trans content of canola at a minimal 0.2%, research at the University of Florida at Gainesville found trans levels as high as 4.6% in commercial liquid oil. The consumer has no clue about the presence of trans fatty acids in canola oil because they are not listed on the label.

A large portion of canola oil used in processed food has been hardened through the hydrogenation process, which introduces levels of trans fatty acids into the final product as high as 40%. In fact, canola oil hydrogenates beautifully, better than corn oil or soybean oil, because modern hydrogenation methods hydrogenate Omega 3 fatty acids preferentially and canola oil is very high in Omega 3s. Higher levels of trans fats mean longer shelf life for processed foods, a crisper texture in cookies and crackers—and more dangers of chronic disease for the consumer.

But most of the Omega 3s in canola oil are transformed into trans fats during the deodorization process . . .

At least it can be said that canola oil is a good source of monounsaturated fat—like olive oil—and therefore not harmful. . . . Or is it? Obviously monounsaturated fatty acids are not harmful in moderate amounts in the context of a traditional diet, but what about in the context of the modern diet, where the health-conscious community is relying on monounsaturated fats almost exclusively? There are indications that monounsaturated fats in excess and as the major type of fat can be a problem. Overabundance of oleic acid (the type of monounsaturated fatty acid in olive and canola oil) creates imbalances on the cellular level that can inhibit prostaglandin production. In one study, higher monounsaturated fat consumption was associated with an increased risk of breast cancer.

Wise Traditions in Food, Farming and the Healing Arts, Summer 2002

that was artificially manipulated to remove its EFAs. Natives living in the tropics who consume enormous amounts of coconut products have among the lowest rate of heart disease in the world.

The oil extracted from a coconut can tolerate high heat. Its naturally-occurring saturated fat enables the oil to resist high temperatures without being transformed into dangerous *trans*—short for “transformed”—fats (discussed in more detail later in this chapter). Incidentally, coconut is one of the few foods besides human breast milk that contains *lauric acid*. Lauric acid has potent antimicrobial properties, which suggests that coconuts may help those afflicted with infections—including cancer, *Candida albicans*, and HIV. Coconut *milk*—the watery, sweet, electrolyte-rich fluid inside the hard coconut shell—has a similar nutrient composition to human breast milk, which makes it suitable for nursing babies.

Flax contains estrogenic plant compounds, which may induce unwanted hormonal fluctuations in some people. Although flax is high in beneficial anti-inflammatory Omega 3 fats, the Omega 3s must be converted by the body before they can be used. Many people (and all dogs) lack the enzyme involved in this conversion. (The enzyme is impaired by elevated insulin levels, by the way.) Therefore, it may be best to obtain Omega 3s from animal sources. As for Omega 6 fats, they tend to be very common in the diet—most seeds and nuts contain generous amounts—so the 6s should be balanced with at least half their amount of 3s, and supplemented with Omega 9s (in olive, macadamia, and sea buckthorn oils).

The best fats have an impressive track record: grass fed animal fat, raw butter from the milk of grass fed animals, olive oil, and coconut oil. Fatty fish like salmon and tuna are problematic. They contain many healthful oils, but because they’re high on the food chain, they have ample time to absorb mercury into their fat. This is why many health professionals recommend that people take their fish oil in the form of capsule or liquid supplements that have been molecularly distilled to remove heavy metals.

The benefits of fish oil have been heavily debated in some circles. Biologist Ray Peat cites studies showing that even the freshest fish oil, with antioxidants added, is unstable and deteriorates within 48 hours. Peat asserts that although isolated fish oil may initially be helpful, over longer periods the oil destroys Vitamin E in the body and suppresses immune function. Are favorable-outcome studies on fish oil flawed because they weren’t conducted for long enough periods for researchers to see a marked increase in inflammatory diseases? Did the animals who enjoyed increased longevity live longer only because they were reluctant to eat the oil-laced food and therefore ate

less? Dr. Peat also reports that some animals fed fish oil developed malfunctioning T cells (immune cells from the thymus gland) that did not protect them from bacterial infections as well as coconut oil did. Nevertheless, many practitioners report huge benefits from fish oil; so if you take it, make sure it’s fresh. If you eat fatty fish, include plenty of vegetable fiber with your meal. The fiber binds to mercury in the gut, and is then excreted with the feces.

Some people are helped by an oil supplement made of krill (tiny shrimp), which is easily absorbed and contains high levels of antioxidants. However, as some whales depend on krill for their main diet, the large numbers caught for human supplementation may not be sustainable. An excellent source of Omega 3 fats is grass fed beef.

Grains

In most traditional cultures, wheat is not a staple. For starch, native peoples have usually eaten rice; maize (also known as corn); dried and pounded roots and tubers such as cassava (tapioca); or soaked, dried and ground seeds such as amaranth and teff. The most popular grains in North America are wheat, rice, rye, oats, barley and corn.

All grains possess an outer indigestible hull. This hull contains *phytic acid*, a naturally-occurring preservative that prevents the kernels (or “berries”) from rotting if they don’t encounter a favorable germinating environment. Phytic acid also binds to minerals in the intestinal tract, preventing them from being utilized. Enzyme inhibitors, which prevent germination under unfavorable conditions, impede digestion in those who eat the grains.

Another problem with grains (a good example of which is wheat) is that the hull contains anti-nutrients that induce the eater to defecate before the seed can be digested. The hull also contains *lectins*, which discourage bacteria, molds and animals from consuming the kernel so the seed can still germinate after years of dormancy. These lectins—which also, by the way, are present in legumes (peas, beans and lentils)—impair metabolism. Usually the damage isn’t detected until it’s severe and crippling.

All of these natural substances are biochemical defenses designed to ensure the survival of the plant. However, the very plant chemicals that allow a seed to grow are precisely what make it indigestible. Therefore, consuming the bran and germ means deliberately eating plant compounds that exist solely to irritate or poison predators. This is why some people soak grains overnight before cooking them. (Sometimes they sprout the seeds, which considerably lessens the amounts of anti-nutrients.) For other people, however, not even long periods of soaking the grains can neutralize or transform the injurious compounds enough to make the grains easy to digest or safe to eat.

Despite issues with the indigestible bran and hull, the natural foods movement routinely promotes whole, or *unrefined*, grains. *Refined* grains are stripped of the outer germ and bran, leaving only the starchy white center (endosperm). The absence of perishable ingredients—virtually all vitamins, minerals, delicate natural oils and fiber—allows refined grains to remain on a shelf indefinitely. This means they can't support life. In experiments with rats and other animals, they die quickly when fed a steady diet of refined grains. When humans eat refined grain, the body draws on its own store of nutrients to process the empty-calorie starch. Nevertheless, some people who react badly to whole grains can eat refined flours with no obvious ill effects—undoubtedly because they're avoiding the noxious chemicals in the hull and germ.

The apparent lack of symptoms when eating refined flour doesn't mean that it's good for you. Aside from the lack of nutrients, most commercial breads, cakes, pies, and pastas are made from refined wheat flour that's been bleached a dazzling white. The toxic bleaching agents (chlorine or nitrogen oxides, potassium bromate) combine with the few remaining proteins in the starchy endosperm to produce *alloxan*. Alloxan destroys the beta cells of the pancreas, making it impossible for the gland to produce sufficient insulin. "Scientists have known of the alloxan-diabetes connection for years," writes Dani Veracity. "In fact, researchers who are studying diabetes commonly use the chemical to induce the disorder in lab animals. . . . Even though the toxic effect of alloxan is common scientific knowledge in the research community, the FDA still allows companies to use it when processing foods we ingest."⁷²

All grains have a high carbohydrate content. They affect the body like sugar (see the next section on sweeteners), and wheat is the most harmful. Humans are biochemically more equipped to handle animal protein, roots, leaves and fruits than grains, as agriculture occurred much later in history than did hunting and the gathering of wild foods.

Many people suffer health problems especially when they eat wheat and its relatives. These grains contain storage proteins called *prolamins*, which are utilized by the plant when it grows. (Other grains contain different storage proteins that aren't as problematic.) Prolamins, soluble only in alcohol, can't be broken down by stomach acid and impair our ability to digest protein. *Gluten*, a glue-like complex containing the prolamin *gliadin*, is the best known toxic plant compound, although there are many more. Wheat, the most common grain in the world, contains the highest levels of gluten. It's also adulterated, and thus causes unlimited health problems (see Insert, "Wheat: Not a Healthy Choice").

Here are some popular grains and grain-like seeds. The first four contain highly problematic prolamins.

- ◆ *Wheat*. Contains the prolamin *gliadin* within the much larger *gluten* complex. There are many varieties of the *Triticum* or wheat family: spelt, kamut, durum, and frumento. Ancient heirloom varieties of wheat are einkorn (the original simple grain) and its more complex descendent emmerwheat. Farro is a dish containing the berries of these ancient varieties. (Wheat *grass* and barley *grass*—juiced for their chlorophyll and nutrient content—are not the grains, but the sprouted green grasses of the young plants. They don't contain prolamins during their first eleven days of growth.) Manufactured wheat products include pasta (compressed, usually refined wheat flour made into noodles of various shapes), orzo (rice shaped pasta), semolina (the starchy inner kernel of durum wheat), couscous (pasta made from semolina), farina (made from the starchy inner kernel, minus the bran and most of the germ), freekeh (roasted green durum wheat), and bulgur (boiled and dried). Wheat is also referred to as graham, cake flour, or simply "flour." Wheat-derived products include hydrolyzed wheat protein, wheat starch, and wheat germ. Seitan, prized by many vegetarians, is the most glutinous portion of the grain, processed into its stickiest possible mass and cooked to resemble meat.
- ◆ *Barley*. Contains the prolamin *hordein*. Products made from barley include "pearled" barley, barley malt (sometimes simply called "malt"), and beer.
- ◆ *Rye*. Contains the prolamin *secalin*. It's in the same family as wheat, although some people find it less problematic than wheat.
- ◆ *Triticale*. A hybrid of wheat and rye, triticale contains prolamins from both.

The following grains also contain prolamins, although they cause far fewer problems than those of the first group.

- ◆ *Oats*. Contains the prolamin *avenin* in very small amounts, which is well tolerated by most people.
- ◆ *Corn / Maize*. Contains the prolamin *zein*, which for some people is a problem. Different corn varieties have different amino acid profiles. Yellow and white corn contain high levels of arginine (which feeds the *Herpes* virus). Blue corn contains high levels of lysine (which inhibits *Herpes*) and low arginine levels. Some people who can't handle yellow or white can tolerate blue.
- ◆ *Sorghum*. Contains the prolamin *kafirin*. It may cause gut issues, though much fewer than those from gluten.

The following don't contain prolamins, although they do contain other (far less problematic) storage proteins.

Wheat: Not a Healthy Choice

Injurious, Not Essential

There's an old saying, "Bread is the staff of life." People "break bread" when they are invited to share a meal. The word "bread" suggests something so basic, it has even become a slang term for money. But is bread really as important as history claims?

Bread is indeed significant, but for different reasons than we might think. In the Western world, bread is synonymous with wheat. So are cake, pie, pastry, and pasta. However, according to many physicians' clinical experiences and solid scientific research, wheat is a poison. We can no longer ignore the compelling evidence of a long list of conditions that are exacerbated or (more often) outright caused by gluten and other toxic compounds. Let's first take a look at what wheat really is.

Botany Basics and the History of Human Tampering

Wheat is a grass, and the seeds on top of the grass stalks are what we refer to as "grains." Einkorn (*Triticum monococcum*), the most ancient wheat, was nothing like its modern counterpart. The DNA of einkorn was simple, containing only 14 chromosomes. Lacking the complex sticky proteins of modern wheat, einkorn could never have formed the breads, bagels, pastries and crullers that people love to eat today. In fact, bread made with einkorn was not only significantly less elastic and sticky, it was somewhat crumbly.

At some point einkorn either naturally cross-bred or was cultivated with goatgrass, an unrelated wild grass (*Aegilops speltoides*), to produce emmer wheat (*Triticum turgidum*). The DNA structure of emmer became slightly more complex, at 28 chromosomes, because unlike humans, animals and many other plants, when wheat is hybridized it *adds on* the genetic material of its "parents." For thousands of years, einkorn and emmer were popular until emmer wheat cross-bred—probably naturally, in the wild—with another type of goatgrass (*Triticum tauschii*). This birthed *Triticum aestivum*, which is genetically close to our modern wheat with a chromosome count of 42. This newer *Triticum* wheat had a much higher yield. It also contained stickier proteins, making it more desirable than einkorn and emmer for baked goods.

When pioneers brought *Triticum aestivum* from Europe to the Americas in the 1600s, wheat underwent another radical change, this time caused by humans. The settlers bred a plant that would survive extreme temperatures, resist drought and disease, and yield more per acre. The original tall grass, which had required a long maturation period, was now dwarf with a rapid growth cycle. In addition, its larger seeds, rather than clinging to their stalks, could be shaken off easily for harvesting.

The most radical alterations to *Triticum aestivum* began in the 1940s, when scientist Norman Borlaug spent almost two decades changing wheat's DNA structure to produce even greater yields. This modern wheat comprises 99% of wheat grown worldwide today, with thousands more genes than what existed in the original plant. In fact, modern wheat hybrids contain proteins that didn't even exist in its *parents* one generation ago! It shouldn't surprise us that these new proteins are biologically incompatible with the digestive tract, immune cells, cardiovascular structures, and every other system—not only in humans, but in animals too. Although the breeding was done manually, the effects were similar to those produced when plants are genetically engineered. Thousands of new strains of modern wheat have become integrated into our food supply, but none have ever been tested for safety. In *Wheat Belly*, cardiologist William Davis writes that:

the incredible financial bonanza that the proliferation of wheat in the American diet has created for the food and drug industries can make you wonder if this "perfect storm" was somehow man-made. Did a group of powerful men convene a secret . . . meeting in 1955, map out an evil plan to mass-produce high-yield, low-cost dwarf wheat, engineer the release of government-sanctioned advice to eat "healthy whole grains," lead the charge of corporate Big Food to sell hundreds of billions of dollars worth of processed wheat food products—all leading to obesity and the "need" for billions of dollars of drug treatments for diabetes, heart disease, and all the other health consequences of obesity? . . . in a sense that's exactly what happened.⁷³

Several Nasty Compounds

All grains / seeds contain storage proteins—a combination of amino acids, minerals, and other substances that exist to help the plant when it's first growing. Especially problematic storage proteins, *prolamins*, are in wheat, rye, and relatives of wheat. *Gluten*, the most well known protein complex, contains several different prolamins (one called *gliadin*), all of which impact very negatively on our health. Gluten protein structures repeat, which creates strong dough. And gluten's tenacious, glue-like stickiness makes it ideal for bread and other fun baked products. But this long stretchy adhesive quality contributes to, and causes, unlimited health problems—ranging from gastrointestinal ailments to degenerative diseases to autoimmune disorders. Following are some of these health conditions and why they occur.

Celiac, the Most Well-Known Affliction from Wheat

The most obviously causative (and well known) health condition related to gluten is *celiac disease*, sometimes called *celiac sprue*. In popular culture, wheat intolerance is synonymous with celiac disease. "The apparent increase in celiac disease (or at least the immune markers to gluten)," writes Davis, "is not just due to better testing: The disease itself has increased in frequency, fourfold over the past fifty years, doubling in just the past twenty years. [This fact] reflects the changes that wheat itself has undergone. Not having celiac disease at age twenty-five does not mean you cannot develop it at age forty-five."⁷⁴

Celiac is a condition of the small intestine, affecting the millions of short, tiny, slender, pole-like projections called *villi*. Villi increase the surface area of the small intestine, allowing nutrients from digested food to enter the bloodstream more efficiently. However, exposure to gluten causes the villi to malfunction. First they become compressed, with somewhat less surface area available for nutrient absorption. As their deterioration continues, the villi become flat, completely destroyed by lesions. Usually the intestinal damage occurs in the duodenum (the first third of the small intestine located next to the stomach); but in advanced cases, the jejunum (the next section of the small intestine) is also damaged.

If the villi are impaired, undigested food remains in the small intestine and ferments. This encourages a overgrowth of *Candida albicans*, which is a fungus. Normally, *Candida* levels are low due to beneficial intestinal flora that eat the *Candida*. But in a gut increasingly toxified by harmful bacteria that cause unhealthy fermentation, the levels of beneficial bacteria dwindle and *Candida* proliferates. *Candida* infections cause almost unlimited problems, ranging from brain fog and depression to severe gastrointestinal disorders and weight gain. Note that gliadin contains amino acid sequences that resemble those in *Candida*, and both gluten and *Candida* stick to the gut in a similar manner.

Even if damage to the villi is only moderate, there are major repercussions to the gut. The body responds to the presence of gliadin by releasing a protein called *zonulin*. A 2008 article on gut permeability in the *Scandinavian Journal of Gastroenterology* discusses how "zonulin signaling" activated by gliadin intake leads "to increased intestinal permeability to macromolecules."⁷⁵ Zonulin is like a doorman: it not only opens the normally tight junctions between cells, it *keeps* them open. This allows excessively large particles from grains and other foods to slip through the holes in the gut, circulate throughout the bloodstream, and enter tissues where, as irritants, they cause further damage. This punctured gut, called *leaky gut syndrome*, is an aberration because the digestive tract is designed to absorb nutrients *through the cells* of the intestinal wall, not through *gaps between the cells*.

One might expect zonulin levels to increase during the acute phase of celiac. But so-called normal people who don't have celiac disease also produce zonulin; the junctures between their intestinal cells simply close more quickly. So even if their villi don't flatten or develop lesions, gluten still damages the intestinal wall by creating holes. Irritation of the gut that occurs independently of villi destruction can cause bloating, gas, chronic diarrhea, and constipation. Extremely high levels of irritation lead to inflammation and potential infection, to which doctors give names such as "acid reflux," "Irritable Bowel Syndrome (IBS)," "colitis," and "Crohn's disease." People with celiac have a 30% greater chance of developing cancers, especially of the gastrointestinal tract.

Despite the obvious symptoms of celiac disease, it can still be difficult to diagnose and treat it because people don't always suffer from the overt intestinal issues that have become synonymous with "celiac." Celiac doesn't always affect the intestines, or affect *only* the intestines. It can also cause neurological impairment, including loss of balance and even dementia. Davis suggests that celiac sufferers who don't have intestinal symptoms should receive the diagnosis of "immune-mediated gluten intolerance" because all symptoms share the same genetic markers. Because immune-mediated gluten intolerance can consist of much more than intestinal difficulties, celiac disease is actually a subset of a larger problem.

One of the reasons 1,800,000 Americans don't know that they have celiac disease is that it is "The Great Imitator" . . . expressing itself in so many varied ways. While 50 percent will experience the classic cramping, diarrhea, and weight loss over time, the other half show anemia, migraine headaches, arthritis, neurological symptoms, infertility, short stature (in children), depression, chronic fatigue, [weight gain] or a variety of other symptoms and disorders that, at first glance, seem to have nothing to do with celiac disease. In others, it may cause no symptoms whatsoever but shows up later in life as neurological impairment, incontinence, dementia, or gastrointestinal cancer. . . . So, even if you have happy intestinal health . . . you can't be sure that some other body system is not being affected in a celiac-like way.⁷⁶

It takes an average of eleven years from the onset of symptoms to a diagnosis of celiac (during which time one can become highly malnourished, causing a host of other problems). In his decades of experience, Dr. Davis has observed that the vast majority of his clients who lack the genetic markers for celiac disease nevertheless become completely well as long as they avoid eating wheat.

Non-Celiac Gluten Sensitivity due to Eating Wheat, Rye, Barley, Spelt, Kamut and Triticale

Immune Response Malfunction. Gliadin can stimulate an *autoimmune condition*, which is characterized by the body's attack on its own tissues. In order to understand why this occurs, we need to briefly look at how the body deals with pathogens.

Antigens are molecules—usually comprised of complex proteins from pathogenic waste or biological tissues—that stimulate antibody production. *Antibodies* are proteins in blood and other fluids that act as the body's defense team. They're produced by different types of white blood (immune) cells in response to foreign substances such as bacteria, fungi and viruses, in order to neutralize them. In a healthy person, the presence of antigens stimulates the production of antibodies. Antibodies, which fit antigens like a key fits a lock, identify the antigens and tell the rest of the body what to do with them. Immune cells remember previous encounters and "teach" other immune cells to recognize the same types of bacteria, viruses or fungi in case of future invasions. So, during an immune response, the body recognizes what is not-body. The immune cells targets, attack, remove, and remember the invader. This is a great strategy for infections.

The problem is, sometimes the body isolates an antigen from a food and *treats the food as the invader*. The immune cells, unable to distinguish between (for example) gliadin and another foreign protein that belongs to a bacterium or virus, develops antibodies against the gliadin. Why would the body respond to gluten proteins as though they're pathogens? *Pathogens have an adhesive quality and can cling to cell membranes. Gliadin is similarly sticky, and attaches to the villi in the gut.* This causes the immune cells to attack the person's own gliadin-ridden body tissues. In *Dangerous Grains*, physician James Braly and Ron Hoggans write:

Whenever an individual's immune system is mounting an abnormal reaction to gluten, with or without symptoms, there is gluten sensitivity. . . . Non-celiac gluten sensitivity, or immune reactions to gluten, may affect . . . a large population that is chronically ill, unresponsive to conventional therapies, and often desperately jumping from one doctor to another without relief. To further confound the issue . . . [they] suffer a greater risk of infectious disease.⁷⁷

Although wheat is the most problematic grain from the standpoint of gluten, its botanical relatives—rye, barley, spelt, kamut and triticale—are challenging too. Also, a faulty immune response can occur to more than one protein in a grain. This is a key point that I'll be discussing shortly.

Statistics compiled by Braley and Hoggan show that autoimmune conditions occur in as high as 42% of the gluten-sensitive. The majority of sufferers develop antibodies to their own thyroid gland and pancreas. Conversely, about 65% of people with autoimmune conditions who get tested for gluten sensitivity, test positive. Common to all the research is an elevation of gliadin antibodies (indicating some form of autoimmune condition), but *without obvious intestinal damage or the presence of celiac disease*. Clearly, gluten is one of the most important factors in triggering or directly causing an autoimmune condition.

Inflammation and Addictions in the Brain. Gliadin grains, particularly wheat, negatively affect brain function. Normally, the brain is protected by the *blood-brain barrier*, tightly clustered cells that selectively allow beneficial substances in but keep harmful substances out. Sometimes this barrier doesn't function properly. Zonulin, the protein produced by the body in response to gliadin, separates the cells of the blood-brain barrier just as it separates the cells of the mucosal intestinal lining. What happens, then, if foreign particles penetrate the blood-brain barrier?

Wheat and other high-gluten grains create *free radicals*—wild, unbound electrons—that penetrate the brain, damage tissue, and cause inflammation. Glutinous grains also contain morphine-like compounds called *exorphins*, or "exogenous morphines." (This is in contrast to *endorphins*, natural morphines produced *endogenously*, or by the body itself.) These exorphins, also called *opioids*, exert a narcotic-like effect by binding to the brain's naturally-occurring opiate receptors. Any condition of the brain and nervous system can be worsened or created: difficulties in balance, muscle coordination, sensation and cognition; fluctuating emotions; even memory loss. Gluten contains at least five different exorphins. Not surprisingly, MRI scans have revealed abnormalities in the white matter of the brain due to these exorphin compounds. When wheat is removed from the diet of people with dementia, their memory and ability to learn improve. So do their MRIs.

Exorphins—whether from a drug or from wheat—are addictive. Thus, what began as a *craving* for bread, cake, donuts, pastries, pies or breakfast cereal quickly escalates into an *addiction* to grains, especially wheat. After eating pizza, pastry or a sandwich, one may feel doopey, brain-fogged or drunk (as though from alcohol).

Despite all this damning evidence, people who are addicted to wheat and other grains, even when advised of the dangers of this drug-disguised-as-a-food, are reluctant to quit. They might deny experiencing any ill effects. Or, if they confess to feeling ill effects and even admit that they're hooked, they often become outright hostile at the suggestion of quitting.

Insulin Resistance, High Blood Sugar, and Obesity. We have learned that wheat is heavily addictive because it contains several morphine-like compounds. But what also contributes to wheat's addictiveness is its singular ability to raise blood sugar. In fact, just two slices of refined wheat or whole wheat toast raise blood glucose levels more than one candy bar or a serving of soda can. Let's look at the nature of carbohydrates as a starting point for this domino effect of health problems.

The public is repeatedly assured that complex (as opposed to refined) carbohydrates are good for us. However, what we aren't told is that there are several different types of complex carbohydrates. Not all of them are nourishing and some are outright harmful. *Amylopectins*, comprised of branching glucose units, are one form of complex carbohydrates. Different types, labeled "A," "B" and "C," have different levels of digestibility. Some amylopectins are indigestible fiber and are simply excreted. Others are easily digested in the stomach and rapidly enter the bloodstream. The most digestible form, amylopectin-A, is found in wheat. It's so readily absorbed that it enters the bloodstream almost immediately, propelling blood glucose to dangerously high levels.

Normally, in response to an increase in blood sugar, the pancreas secretes insulin, a hormone designed to drive the glucose into tissue cells where it's used as fuel. However, if very high-carbohydrate or sugary foods are eaten, blood glucose levels rise too rapidly. The pancreas overreacts and produces too much insulin, which excessively lowers blood sugar levels. In response to low blood sugar, one becomes hungry—and what's usually eaten is quickly metabolized carbohydrates or sweets. This causes the pancreas to produce more surplus insulin. Blood sugar levels drop too low, and the vicious cycle repeats all over again. If this happens frequently enough, after a while the pancreas may weaken, unable to produce enough or any insulin. Often, the tissue receptor sites to insulin can no longer receive insulin's signals and the person becomes *insulin resistant*.

Glucose that can't enter the tissues remains in the bloodstream. This is high blood sugar or diabetes. Higher than normal blood sugar levels, even if not high enough to provoke full-blown diabetes, eventually create *visceral fat*, or adipose tissue surrounding the organs in the abdominal region—what Davis calls "wheat belly."

Visceral fat filling and encircling the abdomen of the wheat belly sort is a unique, twenty-four-hour-a-day, seven-day-a-week metabolic factory. And what it produces is inflammatory signals and abnormal cytokines . . . [leading to pain, and abnormal levels of] cell-to-cell hormone signal molecules, such as leptin, resistin, and tumor necrosis factor. The more visceral fat

present, the greater the quantities of abnormal signals released into the bloodstream. . . . As visceral fat increases, its capacity to produce protective adiponectin [a hormone from fat cells that regulates fat and glucose metabolism] diminishes . . . Wheat belly fat . . . is not just a passive repository for excess pizza calories; it is, in effect, an endocrine gland much like your thyroid gland or pancreas, albeit a very large and active endocrine gland. . . . A wheat belly is not just unsightly, it's also dreadfully unhealthy.⁷⁸

Excess insulin causes unlimited damage. It eventually triggers fatty acid synthesis in the liver, which pours triglycerides into the bloodstream. The triglycerides turn into VLDL (very low-density lipoprotein) particles—otherwise known as "bad" cholesterol, the kind that deposits plaque on artery walls and restricts the passage of blood. High blood sugar causes the destruction of bone and cartilage tissue due to its inflammatory properties. High blood sugar is also related to acne. Insulin stimulates the release of a hormone (insulin-like growth factor-L) within the skin, which overstimulates the production of oil and causes pimples. And, as many diabetes sufferers already know, high blood sugar can lead to kidney failure and limb amputation.

People who develop fat around their midline are susceptible to blood sugar imbalances, even if they don't (yet) have symptoms or a diagnosis of diabetes. Avoiding wheat is about more than simply eliminating gluten.

Advanced Glycation End Products (AGEs). The acronym AGEs is appropriate. *Advanced glycation end products* are proteins whose structures and functions are radically and undesirably altered when they react with sugars. As long as glucose isn't used by the body for fuel, but instead circulates in the bloodstream—as with abnormally high blood glucose levels or a full-blown case of diabetes—more AGEs are produced and more accumulate. AGEs make arteries stiff (atherosclerosis), cloud the lenses of the eyes (cataracts), destroy nerve tissue (dementia and loss of sensation), cause heart disease and kidney damage, and erodes the joint and cartilage. People assume these conditions are "normal" effects of aging. They are not. They are, however, the expected, gruesome results of AGEs.

Summary. Here is just a brief overview of conditions not only exacerbated by wheat and some other grains, but in many cases, directly caused by them.

- ◆ Allergies of all kinds.
- ◆ Arthritis, rheumatoid arthritis, fibromyalgia, and other types of chronic joint and muscle pain.
- ◆ Bone defects: tooth enamel erosion, impaired bone growth (and thus short stature), and osteoporosis.

- ◆ Cancers of all kinds, including of the bladder, brain, prostate and testicles, as well as Lupus erythematosus, lymphoma, and squamous cell.
- ◆ Cardiovascular ailments, including cardiomyopathy (weakening of the heart muscle structure) and recurrent pericarditis (inflammation of the pericardium, which is the lining that surrounds the heart).
- ◆ Digestive tract damage (including leaky gut) and vitamin and mineral deficiencies due to malabsorption or incomplete nutrient conversion.
- ◆ Eyestrain distortions, such as “telescoping” vision.
- ◆ Hormone disruption, including Addison’s disease (insufficient adrenal hormones), diabetes, growth hormone deficiency, and thyroid disorders.
- ◆ Liver diseases.
- ◆ Neurological problems: anxiety, aggression, Asperger’s syndrome, autism, ADD, dementia, depression, dyslexia, epilepsy, hyperactivity, learning disorders, migraines, mood swings, Multiple Sclerosis, seizures, and schizophrenia.
- ◆ Reproductive problems including infertility, abnormal sperm motility, miscarriage, stillbirths, delayed puberty, and menstrual disorders.
- ◆ Respiratory issues such as asthma and emphysema.
- ◆ Skin conditions, including dermatitis, eczema, psoriasis and warts.
- ◆ Urinary tract problems, including kidney disease and frequent urination (sometimes at night, suggesting a possible history of bedwetting).

It makes sense that infections are on this list. Glutinous exorphins can attach themselves to any part of the body and prevent immune cells from scavenging dead bodily cells and incapacitating pathogens. In addition, the high carb content of wheat causes chronically high blood sugar levels, creating a breeding ground for pathogens.

Gluten-Like Problems from Lectins

Lectins—known as *agglutinins* (from the Latin *agglutino*, meaning “to glue to”)—are sugar-binding plant proteins similar to gluten. The most damaging lectins are in legumes (soy, beans, peanuts and some nuts), dairy (especially from grain fed cows), nightshades (eggplant, peppers, tomatoes and potatoes), and grains—especially wheat, rye, barley, corn, millet, and oats. In ways very similar to gluten, lectins can damage the gut, bloodstream, nervous system, organs, and glands in sensitive people. The villi become inflamed, harmful bacteria proliferate, and the intestines leak. Red blood cells clump. The brain develops cognition and motor disorders. Lectins bind to glucosamine (a component of cartilage) and destroy joint

tissue. They diminish the body’s sensitivity to *leptin*—the hormone that signals when we’ve had enough to eat—thus slowing metabolism and producing abnormal fat deposits. Lectins bind to insulin receptors. And they cause autoimmune disorders, inflammation, and AGEs.

Lectins cannot be inactivated completely by heating, soaking, sprouting or fermenting, although these methods do help a bit. (Wheat and its relatives are unaffected, however.) Some doctors have found that by avoiding lectins alone, health and normal weight can be restored.

Wheat Intolerance and Dairy Intolerance

Research shows that 50% of gluten-sensitive individuals are unable to handle dairy products. (However, the research doesn’t distinguish between commercial adulterated dairy and raw, grass fed, and / or A2 dairy.) If a product contains wheat, it will very likely also contain, or at least be eaten with, commercial milk, cream or butter. *The same receptor sites in the body accommodate the proteins from both grain and dairy.*

Adding both dairy and sugar to a wheat item makes the product especially lethal. It’s no accident that the most ubiquitous junk food in the United States is pizza—made with wheat and adulterated dairy (as well as nightshade vegetables). And it’s no accident that favorite desserts (such as cheesecake or cannoli) are made from wheat, dairy, and sugar.

Wheat Intolerance Through Inhalation and Touch

Some people are sensitive to more than the *ingestion* of wheat: one man reported extreme reactions from *inhaling* wheat flour dust in the bakery where he worked. Some people react if they *touch* materials containing gluten. Several building material companies, in the admirable attempt to use alternatives to formaldehyde-ridden particle board, are manufacturing *wheatboard* made of recycled wheat chaff. Although free of synthetic chemicals (as well as being stronger and more moisture-resistant), the board can still be toxic to gluten-sensitive individuals.

Detecting Wheat Intolerance or Allergy

Conventionally trained medical doctors will tell you that there’s a difference between a full-blown immune response to wheat and “merely” an intolerance to it. A few expensive blood tests can detect the presence of immune-related antibodies in the blood that are produced in response to gluten. However—and this is where conventional medical training doesn’t help most gluten-sensitive people—someone can be negatively impacted by gluten without having an antibody response. I have already discussed many common celiac symptoms, including digestive disturbances (bloating and

constipation) and sudden, extreme weight fluctuations. There can be myriad other symptoms too, such as sleep disturbances, alterations of mood, and chronic fatigue.

It can be hard to grasp that grains are problematic because often, symptoms aren't obvious until the foods have been avoided for a month or even longer. Some people choose to undergo tests for the precise antibodies produced in response to gluten allergens or antigens. They may want confirmation of what they already sense—or hope they're wrong about—so they can continue to eat what they want. However, the best way for the body to heal is total avoidance.

Even nursing, wheat-eating mothers may want to rethink their diet. A sensitive nursing child, who receives the offending proteins through the milk, will react as though s/he has eaten the actual wheat. Symptoms will manifest as allergies, colic and other digestive disturbances, crankiness, and sleeplessness. Wheat intolerance can appear in anyone, at any age.

Healing from Wheat-Related Illnesses

It takes a minimum of two years to repair a gut damaged by wheat. After the gut heals, the best way to maintain health is to continue to avoid the grain, and to eat more assimilable, nutrient-dense foods. People who are ill or over 35 or 40 years old are advised by holistic health practitioners to supplement their diet with digestive enzymes—amylase, catalase, protease, lipase and hydrochloric acid—as well as probiotics. Raw fermented vegetables such as sauerkraut provide probiotics. Aloe vera juice, slippery elm bark powder, L-glutamine (an amino acid), and edible clay (such as pascalite or calcium bentonite) between meals can help heal the digestive tract, as can 1 teaspoon of activated charcoal with meals.

If you have autoimmune damage, an even bigger repair job awaits you. You may suffer from heavy metal or fluoride poisoning. Probably everyone will require liver support. See a holistic medical professional.

The good news is, often even severe health problems can completely heal if you avoid wheat and perhaps other grains too. Once you feel better, you'll see that dietary restrictions are a small price to pay for such a huge improvement in your health. *All* intestinal villi flatten when exposed to gluten; so even presumably non-reactive people who don't think they have issues with gluten, require 72 hours to recover after eating it. Therefore, why eat it at all?

Substitutes for Glutinous Grains and Flours

Rice, wild rice, buckwheat, quinoa, amaranth, teff, and many tubers (root vegetables) are healthy and satisfying substitutes for glutinous grains. Tubers can include potatoes, carrots, cassava root, or celery root (which is both delicious and a healthy alternative to other tubers).

Instead of flour, the best sticky alternatives are arrowroot, kudzu, tapioca, chia seeds, potato starch, and teff. Meal or "flours" made from coconut, sorghum, rice, corn, and ground nuts and seeds (pumpkin, almonds, hazelnuts, cashews, chestnuts, peanuts, pecans, walnuts, chickpeas, amaranth, buckwheat, and pea) are less sticky. Almonds, chia seeds, coconut, kudzu, pea flour, pumpkin meal, and teff flours contain beneficial resistant starch, which isn't metabolized in the body as caloric carbohydrate, but feeds the gut flora. For binding, in addition to using some sticky "flours" in your recipes, you can always use beaten eggs or ground flax seeds.

Be aware that there is an issue with the corn, potato, rice, and tapioca starches that we substitute for wheat flour. Although they don't trigger the immune or neurological reactions that wheat triggers, they still cause extreme insulin spikes and abnormal blood sugar levels. In fact, the reactions that these substitutes cause are even more extreme than those caused by wheat! Thus, "gluten-free" doesn't necessarily mean "low-carb." In fact, it's usually very high-carb. People with longstanding problems related to wheat ingestion—especially those who are overweight—would be wise to avoid the most common wheat "substitutes" and wean themselves off high-carbohydrate foods entirely.

Avoiding Gluten Issues By Using Heirloom Wheat

Artisinal sourdough bread bakers insist that people can digest grain if the bread is fermented. They make it the old-fashioned way: the dough sits for longer than 24 hours, during which some of the noxious elements in the grain are predigested. However, even fermentation cannot completely break down all of the indigestible components. Sometimes, the improved health of some artisinal bread customers may also be due to the use of the original, simpler strains of wheat (either einkorn or emmer wheat). Nevertheless, these simple "back to basics" procedures may not be enough.

In the End . . .

Whether modern wheat is organic, stone ground, sprouted or sourdough, it's still wheat, with its gliadin and other irritating proteins, and amylopectin-A. Wheat is addictive, inflammatory, and leads to extreme glucose levels that impair health almost beyond imagination. Research by pathologist Joseph Kraft shows that 60% to 70% of the population is sensitive to carbohydrates. So is it really worth eating wheat—of any kind?

Considering the severity and scope of health problems due to wheat, at this point it seems wise to avoid it entirely—regardless of its origin or how it's prepared. People who are ill shouldn't eat it. People who aren't ill and don't want to be, should probably think twice about eating it. This may be good advice for other grains too.

- ◆ *Rice*. Includes the misleadingly named “glutinous” rice (which is sticky, hence the name). Until recently, rice has been eaten polished. In Asia, where rice is a staple, carbohydrate intolerance wasn’t a problem until modern wheat and processed dairy were added to the diet. Basmati, a fragrant rice that heals the gut, is used in Ayurvedic medicine for digestive disorders. Wild rice is the seed of an unrelated nutty-tasting grass. In prepackaged meals, gluten may be added to rice “to improve consistency,” but this is rarely on the label.
- ◆ *Teff*. The size of a poppy seed and highly nutritious, teff is used to make *injera*, an Ethiopian flatbread.

The following seeds cook and act like grains. Except perhaps for two strains of quinoa, none contain prolamins.

- ◆ *Buckwheat / Buckwheat Groats / Kasha*. This confusingly named food is not in the wheat family at all, but is the seed of an herb related to rhubarb.
- ◆ *Millet*. Commonly fed to birds, this grass seed contains goitrogenous compounds that impair thyroid function and inhibit iodine absorption. The effects *increase* when cooked, so millet should not be eaten often.
- ◆ *Amaranth*. This nutritious seed, botanically related to spinach and quinoa, contains the amino acid lysine.
- ◆ *Quinoa*. Nutritious and botanically related to spinach and amaranth, quinoa contains the amino acid lysine. Two out of 15 varieties of quinoa contain proteins distantly related to gluten, which cause people with celiac disease to react as though they had eaten wheat. However, most people don’t have a problem with quinoa.

Those with longstanding or serious health issues might consider abstaining from grains until health is restored. Everyone could benefit by avoiding most prolamin grains.

Natural, Refined, and Artificial Sweeteners

Humans have always loved sweet foods. The expression “sweet tooth” dates from the late 1300s. Originally, the phrase referred to a fondness for any morsel that was considered a delicacy; but over time, it came to mean *sweet* delicacies. Today, the expression pertains to anyone who has an uncontrollable craving for sweets. Of all the tastes—sweet, sour, salty, bitter and astringent—the sweet taste is the favorite of most people all over the world, particularly children.

Our sense of smell usually lets us know whether we should eat a food. If the animal or plant smells rancid or putrid, it’s very likely rotten or poisonous; and if it’s sweet, it should be okay to eat. However, what tastes

intoxicatingly sweet isn’t always good for us, and we pay dearly with our health. So-called natural sweeteners straddle the line between real and manipulated food because although most are derived from natural plants, their sweetness is concentrated through drying, heating, or evaporation. These changes affect body chemistry in ways that aren’t beneficial.

There are many types of sugar. Among the ones ending in “ose” are dextrose, fructose, galactose, glucose, lactose, maltose, and sucrose. (Glucose is the primary fuel utilized by the brain and muscles.) Among the sugars ending in “tol” are those classified as sugar alcohols or polyols: erythritol, lactitol, maltitol, mannitol, sorbitol, and xylitol. Different foods contain different amounts and combinations of sugars. For example, refined white sugar from cane is almost 100% sucrose (which is broken down by the body into glucose and fructose), the sugar in apples is almost 100% fructose, and different honeys usually contain varied proportions of fructose and glucose.

In this discussion on sweeteners, I will explore in depth the effects on the body of all types of sugars. Then I’ll discuss specific sweeteners, from the least processed to the outright artificial. “Least processed” refers to substances that are gathered from nature, and then dried or heated to concentrate their sweetness. “Outright artificial” refers to substances that are synthesized in a lab. They might be extracted from natural materials, but they undergo so many chemical processes that they’re ultimately transformed into entirely different substances.

The Bitter Truth About Sugars

Unless specified, “sugar” includes *all* sweeteners except for the obviously artificial sugar substitutes. Sugar:

- ◆ Promotes tooth decay (except for xylitol).
- ◆ Upsets the body’s vitamin and mineral balances.
- ◆ Feeds harmful microbes.
- ◆ Suppresses immune response.
- ◆ Permanently alters protein structure and function.
- ◆ Causes a loss of tissue elasticity and function.
- ◆ Changes collagen structure.
- ◆ Causes tendon brittleness.
- ◆ Impairs DNA structure and function.
- ◆ Causes hormonal imbalances.
- ◆ Hinders normal cell metabolism.
- ◆ Interferes with oxygen availability to the body.
- ◆ Destroys enzymes.

It's not surprising, then, that sugar exacerbates or directly causes virtually unlimited problems in all aspects of biochemical and physiological functioning. Aside from general fatigue, low energy and high stress, more specific problems include infections and chronic degenerative conditions, including:

- ◆ Autoimmune conditions (including arthritis, asthma, and Multiple Sclerosis).
- ◆ Blood sugar problems (diabetes and hypoglycemia).
- ◆ Cancers, many types (brain, breast, colon, ovary, prostate, stomach, etc.)
- ◆ Cardiovascular problems (varicose veins, heart problems, and atherosclerosis).
- ◆ Eye issues (including cataracts and nearsightedness).
- ◆ Gastrointestinal problems (including food allergies, chronic indigestion, ulcerative colitis, Crohn's disease, and *Candida albicans* overgrowth).
- ◆ Nervous system disorders (anxiety, depression, mood swings, hyperactivity, difficulty concentrating, and increased risk of polio and epileptic seizures).
- ◆ Respiratory tract problems (including emphysema).
- ◆ Skeletal structure debilitation (such as bone loss, due to decreased ability to absorb calcium and magnesium).

Tooth decay is probably the most well known, and least contested, consequence of eating sugar. It is popular knowledge that bacteria in the mouth (primarily *Streptococcus mutans*) feed on sugars, and the acids secreted by bacteria erode the dental enamel. But what about the other health problems?

Nutrient Depletion. *Sweeteners, regardless of their source, deplete our nutrient reserves.* Some sweeteners contain absolutely no nutrients (such as white “table sugar” sucrose); others, such as molasses and honey, contain some. But even the most nutrient-rich sweetener doesn't contain enough vitamins and minerals to process the sugar. *The body requires huge amounts of vitamins and minerals to process simple sugars.* When we eat sugar, the body is forced to steal from its own stores of minerals and vitamins (including many of the B-complex vitamins) to metabolize it. Often those stores are already scarce or non-existent, particularly in those who are ill. This is why sugar is referred to as an *anti-nutrient*. Nutritionally starved cells malfunction and die sooner, have poor resistance against pathogens, and age and die more quickly due to oxidative damage—thus promoting an increase in all kinds of disease.

Normally, Vitamin C helps prevent oxidative damage to the cells. However, *Vitamin C is particularly susceptible to being displaced when sugar is eaten because it shares, with sugar, the same metabolic pathway into the cell.* As Vitamin C is made directly from glucose, it has a similar chemical structure to sugar. This may explain why *only* Vitamin C, or *only* sugar, can enter a cell at a given time. If sugar and Vitamin C are competing for the one available transport system, even a slightly higher amount of sugar compared to Vitamin C will prevent the vitamin from reaching the tissues. Vitamin C has another important feature too: it helps strengthen the cell membrane, allowing nutrients to enter and wastes to leave. When Vitamin C is scarce, metabolic wastes quickly accrue, providing a breeding ground for bacteria, fungi and viruses that enter the cell effortlessly. With such easy access to the tissues, plus extra sugar to feast on, the pathogens readily proliferate, practically guaranteeing the onset of disease. Nutritionist Bill Misner elaborates.

Vitamin C is made in almost all living mammals except humans and a couple other species. . . . We've known for many years that sugar depresses the immune system. . . . It was only in the 70s that they found out that vitamin C was needed by white blood cells so that they could phagocytize [scavenge and eliminate] bacteria and viruses. . . . Linus Pauling knew that white blood cells needed a high dose of vitamin C and that is when he came up with his theory that you need high doses of vitamin C to combat the common cold. . . .

There is something called a phagocytic index which tells you how rapidly a particular macrophage or lymphocyte can gobble up a virus, bacteria, or cancer cell. . . . *If there is more glucose around there is going to be less vitamin C allowed into the cell and it doesn't take much. A blood sugar value of 120 reduces the phagocytic index 75%. [emphasis added]*⁷⁹

Another key nutrient that the body uses to metabolize sugars and starches is Vitamin B1 (thiamine). Symptoms of thiamine depletion include irritability, moodiness and inability to concentrate, because the brain and nervous system depend heavily on thiamine in order to function.

Hormone Malfunction. Earlier in this chapter I described some of the complex interactions between various organs and glands when caffeine is ingested. A similar response occurs with concentrated sweeteners, in part due to their lack of fiber. Let's use fruit as an example. When we eat an apple, the fiber or pulp is ingested along with the sugars. Fiber acts as a buffer in the intestinal tract, preventing the sugars from being absorbed too quickly

into the bloodstream; otherwise, blood sugar levels would rapidly rise. (All sugars get transformed into glucose, the form of sugar best utilized by the body.) But with fruit *juice*, the fiber—which ordinarily slows the absorption of sugar—is missing. When the readily absorbed sugar hits the bloodstream, the pancreas over-secretes insulin in an attempt to drive the excessively high levels of glucose from the blood into the cells. This sudden outpouring of insulin then creates *too low* a level of blood glucose, which in turn further stimulates more sugar cravings. In response, the person ingests more sugar, which induces yet another outpouring of insulin. Thus the cycle of high/low blood sugar levels begins all over again.

The pancreas isn't the only gland that malfunctions from sugar distress. So do the adrenals, which secrete hormones in response to the alarm state of the pancreas. Most people are familiar with the fight-or-flight function of the adrenals. When we're frightened, angry or anxious, the adrenals secrete adrenaline and cortisol. Adrenaline keeps us alert and focused to help us deal with the danger. Cortisol increases the heart and breathing rates and tenses the muscles, to help us literally fight or flee. When the stressor is removed, adrenaline levels drop. However, because cortisol levels take a longer time to build in the body, they also take a longer time to return to normal. Therefore, after the danger has passed, the cortisol volume still rises a bit more, and remains at that level for a while. During this time, the cortisol signals us to replenish our nutrient stores by *eating*.

The adrenal distress call causes more than overeating. Cortisol also signals the body's fat (adipose) cells to release fats (called *triglycerides*, when released from the fat cells) into the bloodstream, for the purpose of providing energy to the muscles. (Meanwhile, the adrenaline had induced the pancreas to secrete yet another hormone that affects the liver in its sugar-storing capacity. However, this piece will be omitted to avoid making this discussion too complicated.) The problem is, if your muscles aren't moving—if, for example, you're lying on the couch eating chips and watching TV instead of going for a brisk walk—the triglycerides will not be used as fuel. Instead, they'll mostly migrate to the fat cells throughout the body. Some triglycerides go to the liver, but the liver has a limited capacity to store fat; so the excess is sent to the adipose cells. And there can be quite a bit of excess.

Meanwhile the triglycerides, on their way to the body's fat storage units, pass through the blood vessels, where they can easily clog the arterial walls. This is why unused sugars in the body can lead to heart attacks. A high sugar intake can cause as many as 150,000 premature deaths from heart disease alone each year in the US. Sugar also lowers the levels of beneficial high density lipoproteins

Most chronically ill people don't have the energy for strenuous exercise, and are therefore much more susceptible to obesity. If you're chronically ill, you can't afford to be obese, because it further throws off your already battered hormone balance. I like to think of carbs as rocket fuel: a little bit goes a long way. Consume just enough carbs to keep your energy up, but too much causes weight gain, blood sugar and insulin spikes, and excessive inflammation. Carbohydrates are eaten with awareness and intentionality; they aren't the first thing you grab. If you're craving carbs, eat some. Just be sure to stop after you've had enough, and of the right kind.

—adapted from Bryan Rosner,
Freedom From Lyme Disease (2014)

(known as HDL or “good” cholesterol), and raises the levels of harmful low density lipoproteins (known as LDL or “bad” cholesterol). The HDL cholesterol is used for many important bodily functions. The LDL cholesterol forms plaque on the arterial walls, related to heart attacks.

Fatty triglycerides are not the only substances that gravitate to adipose tissue. Cortisol has an affinity for fat as well, especially the adipose tissue deep within the abdominal cavity. This is why even thin people can accumulate abdominal fat, giving them an “apple” rather than a “pear” shape in the midsection. This “beer belly” fat not only indicates high adrenal stress, but it has also been linked to cancer, cardiovascular disease (including high blood pressure and stroke), diabetes, and premature death.

Pancreatic and adrenal function are intricately related. Both cortisone and LDL cholesterol levels rise by a whopping 400% in response to excess blood sugar levels. Over time, the consistent overexertion of both the pancreas and adrenals causes them to become depleted, which contributes to systemic breakdown. This can be greatly eased by better food choices and exercise. As the **Exercise** section later discusses, even a moderate 20-minute daily walk can help eliminate some body fat.

As already mentioned, in response to excess sugar in the blood, the pancreas secretes more insulin to escort glucose out of the bloodstream and into the tissues to be used as fuel. However, too much insulin in the blood can desensitize the insulin receptor sites on the cells. Or, the receptor sites may be completely full and unable to accommodate any more insulin. Or, the receptor sites may fail to recognize the message that the insulin is bringing. All of these malfunctions contribute to *insulin resistance* (which often accompanies chronically high insulin levels). Whatever the reason for the insulin resistance, glucose can no longer enter the cells, and instead accumulates in the blood. In response, the pancreas tries to reduce the blood

glucose levels by producing and releasing yet even more insulin. This is how a malfunctioning feedback loop, if not corrected, turns into full-blown diabetes.

One symptom of diabetes is thirst, which can be caused by the high ratio of sugar to blood. Another symptom of diabetes (and mild insulin resistance as well) is *hunger*. Dr. Batmanghelidj, author of *Your Body's Many Cries for Water*, pointed out that insulin draws water from the extracellular environment (the area surrounding the cells), which causes artificial hunger—and is another contributing factor to the desire to eat more. When the cell receptor sites resist insulin's effects, virtually none of the carbohydrates and sugars that are eaten are metabolized, because they can't get into the cells to be burned as fuel. Instead, as described in *The Nutrition Solution*,

triglycerides continue to be released into the bloodstream to try to make up the energy deficit. Unfortunately, this has the effect of stimulating the liver to synthesize even *more* triglycerides, so that the bloodstream becomes overloaded with them—in addition to the excess glucose and insulin. This process accounts for the excess triglycerides—a prime risk factor for cardiovascular disease—found in people with Syndrome X.⁸⁰

Syndrome X is also known as *Metabolic Syndrome* or *carbohydrate intolerance*. Over one-third of the US population is either obese or overweight, and at least that percentage also has problems managing carbohydrates and sugars. People who are carbohydrate intolerant are insulin resistant, which impacts many functions in a cascade effect. They often suffer from inflammatory conditions caused by excess sugar. Also, many people who are diabetic are insulin resistant and carbohydrate intolerant.

Insulin resistance affects *leptin*, a hormone that was discovered at a US university in 1994 by scientists doing research on mutant mice. This unusual hormone is not secreted by any gland that's part of the conventional endocrine system—but rather, by *white fat cells* in the body. Leptin reduces, or suppresses entirely, cravings for carbohydrates and sweets once it circulates in the bloodstream and latches onto leptin receptors in the tongue and brain. “Leptin is the way that your fat stores speak to your brain to let your brain know how much energy is available and, very importantly, what to do with it,”⁸¹ writes physician Ron Rosedale. Leptin controls appetite and fat storage, and tells the liver what to do with its stored glucose.

In an optimally functioning body, leptin conveys messages to reduce fat storage, increase the burning of fat, and reduce hunger (via feelings of satiation, and the sensation of being full). But if signals are not being sent or

received properly, the biochemical messages from leptin will not register. Note that it takes a very small amount of sugar to upset the body's balance. A study published in a 2017 edition of *Clinical Science* showed that men age 40–65, who considered themselves healthy, had an increased risk of developing cardiovascular disease after adding high levels of sugar to their diets for 12 weeks.⁸²

There are two ways that the leptin regulation system can malfunction and make people overeat. One, there is not enough leptin in the system. Two, high levels of leptin are present—but the receptors aren't working correctly, probably because they've lost their sensitivity to leptin. If the body is exposed to too much leptin over a period of time, it becomes impervious to the signals. It stops burning fat and continues to store fat, thus causing hunger. People (and animals) can become leptin resistant the same way that they become insulin resistant: through the overconsumption of sugars and carbohydrates. This is why leptin is sometimes called the *obesity hormone*. Like insulin, leptin escalates the storage of fat, particularly in the belly. (In the proper moderate amounts, leptin helps promote the growth of bones, cartilage, skin, and gastrointestinal tract tissue.)

Very simple sugars, Rosedale writes, are deleterious “to ideal health and optimal athletic performance when prolonged consumption in amounts above 15% of the carbohydrate calories are ingested.”⁸³ Highly concentrated grains such as flours affect the body in a similar way.

Standard advice is to eat slowly and calmly, and to make sure that breakfast contains concentrated protein. Different sources suggest various strategies to balance leptin, blood sugar, and insulin levels. For example, the authors of *Mastering Leptin* advocate at least 11 to 12 hours between dinner and breakfast the next day and eating three meals a day with no snacks. Alan Christianson, author of *The Adrenal Reset Diet*, suggests snacks for certain individuals, as well increasingly more carbohydrates during the day and especially at night, depending on whether one's adrenal stress (or malfunction) manifests in too little cortisol, too much cortisol, or a faulty timing of cortisol production. Whether an approach will work depends on one's health status and metabolism.

In general, most people eat far too many carbs. This is why there's a chapter in *Mastering Leptin* called “Eat Like a Pyramid, Look Like a Pyramid.” (See Insert, “The Food Pyramid and Carbohydrate Intolerance.”) The growing popularity of the so-called Paleo diet illustrates many people's need to eliminate concentrated carbohydrates from their meals. The Paleo diet allows animal proteins, non-starchy veggies, small amounts of coconut and olive oils, and perhaps berries—with absolutely no grains or even, in the strictest circles, dairy. Most people lose

The Food Pyramid and Carbohydrate Intolerance

The food pyramid—which organizes animal and plant foods into groups, containing grains, beans, fruit, vegetables, milk, meat, dairy and oils—is shown to every schoolchild in America. Developed in the 1960s by the US Department of Agriculture (USDA), it was intended to tell Americans with a single picture what to eat, and how much to eat daily, from each food group. At the base are foods to be eaten in the largest volume, the amounts gradually decreasing as the pyramid narrows to the capstone at the top, at which point foods should be eaten sparingly. The food group at the very bottom is grains, bread and pasta. Oils, fats and sugars occupy the capstone position.

Here is a brief summary of the basic nutrients:

- ◆ **Proteins** (comprised of smaller units called amino acids) support metabolic functions while repairing and building tissue. On rare occasions, they will provide energy when there are not enough carbohydrates or fats available; but the body must perform considerable conversion before the proteins are available for energy needs. Concentrated sources of proteins include red meats, poultry, fish (including shellfish) and eggs.
- ◆ **Fats** support many different types of metabolic functions and provide slow steady energy. They comprise 80% of the nerve tissue and brain. Fats are abundant in fatty meats, poultry and fish, nuts and seeds, full-fat dairy products, fatty vegetables such as olives and avocados, and of course vegetable oils. Moderate amounts of fat help promote a feeling of satiation.
- ◆ **Carbohydrates** (comprised of simple sugars and more complex starches) break down into simple sugars in the body and provide quick, accessible energy. High-carb foods include refined and whole grains and concentrated sweeteners. High- to moderate-carb foods include legumes and beans, some nuts and seeds, dairy products, and starchy roots (potatoes, yams, carrots, parsnips, winter squash, pumpkin). Low-carb vegetables include greens of all kinds, stalks (like celery), and flowers (broccoli, cauliflower). All low-carb vegetables are considered fine for people on a low-carb diet.
- ◆ **Sugars** are processed immediately by the body and provide instant energy. High-sugar foods include fruits, honey and other natural sweeteners, and to a certain extent grains.
- ◆ **Fiber** (soluble and insoluble) passes through the gut undigested. Soluble fiber forms a gel when mixed with liquid, whereas insoluble fiber does not. Fruits, vegetables, *whole* grains, seeds, nuts and beans contain fiber. Animal protein contains almost no fiber.

The USDA recommends six to eleven servings per day of grains, bread and pasta. *Life Without Bread* states:

One of the greatest myths . . . is that you cannot become fat from eating carbohydrates. Yet the production of triglycerides, the form of fat that gets stored in adipose tissue, is a result of excess carbohydrate consumption. If carbohydrates are not used immediately for energy, they are converted by biochemical reactions into triglycerides, or into glycogen (sugar stored in the liver). It doesn't take much to fill up the body's glycogen storage bank.⁸⁴

People aren't told that grains were awarded the position of greatest volume when the pyramid was being formulated because of input from the subsidized grain industry. US dietary habits conform to the USDA pyramid recommendations. Is it any wonder, then, that over half the American population is overweight, and a sizeable percentage morbidly obese? High-carb grain meals are cheap, compared to animal protein and vegetables. But most people cannot handle huge amounts of carbohydrates, whether whole or refined. If excess sugars are ingested, metabolic disorders result.

There are other problems with the food pyramid besides the prominence awarded grains. The USDA recommends two to three servings of protein, from either animal sources or beans/nuts/legumes. Meat, poultry and fish are placed in the same category as beans and nuts, but those proteins are quite different. Meat contains valuable phosphorus, Vitamin B12 and other nutrients; nuts and beans do not. Meats contain virtually no carbohydrates; nuts and beans are loaded with carbs. And animal protein (and fats) digest much more slowly than any carbohydrate. People who absorb sugars quickly into the bloodstream need the slow, steady energy that animal protein provides—they cannot handle the biochemical crashes caused by carbs.

At the pyramid top, fats reside with added sugars as though they belong to the same food group. And no distinction is made between *kinds* of fats. There's a huge difference between fats from clean fish or grass fed meat, and fats from hydrogenated, processed vegetable oils. Finally, at least 30% of our diet should consist of healthy fats, with more for older people. (The North American Inuit diet is often 90% fat.)

Americans are so scared of fat and cholesterol, they are limiting their intake of red meat and eggs instead of insulin-producing carbohydrates. Of all the populations in technologically advanced countries, those in the United States are the most malnourished. In 2006, 8% of the entire US population reported to the National Center for Chronic Disease Prevention and Health Promotion that a doctor told them they had diabetes. And these statistics apply *solely* to those who *knew* about their condition!

The standard food pyramid is a dangerous model. Newer models, which have been issued since the original, follow a similar theme, and are still not correct.

weight eating this way. Only after their body has become balanced might they require more carbs (and be able to handle them).

Impeded Oxygen Transport. Large amounts of glucose cause the deposit of excess fat not only around organs and in the subcutaneous (beneath the skin) fat cells, but also in the blood vessels. This reduces the amount of oxygen available to the red blood cells. When red blood cells are deprived of oxygen, they become sluggish, lose their electrical charge, and start sticking together. “Cellular hypoxia [the lack of oxygen],” Misner points out, “is the constant companion of numerous degenerative diseases.”⁸⁵

Impaired Brain Chemicals. As already mentioned, insulin blocks the action of leptin in the brain. However, sugar also affects the brain in another way: it causes addiction, similar to an alcohol, tobacco, cocaine, or other drug addiction. Parents are well aware of sugar’s allure when confronted by the child who demands more candy and has a temper tantrum if that sugar fix isn’t instantly satisfied. And drug treatment counselors recognize the similarities between sugar and drug addictions, as sugar and alcohol latch onto the same beta endorphin brain receptors. One can stimulate a craving for the other.

There’s a similarity between cocaine, concentrated sugars, and refined carbs. All cause the release of the

neurotransmitter *dopamine*—nicknamed the “feel good molecule”—as evidenced by research such as “Daily bingeing on sugar repeatedly releases dopamine in the accumbens shell [a part of the brain].”⁸⁶ We become addicted to activities or foods that cause dopamine release. The problem is, in the presence of excess insulin our dopamine receptors become fewer and less responsive, causing us to eat more in an effort to induce more dopamine production. Hence, a vicious cycle ensues.

Glycemic Index Propaganda. If sugar damages our health so much, what about foods that *contain* sugar? Are there no sugars (or carbs) that are safe—or safer—to eat?

The *glycemic index* (GI), concocted in 1981 by two researchers at the University of Toronto in Canada, presumably addresses this issue of safety. The index classifies carbohydrates according to how fast they raise glucose and insulin levels in the bloodstream. Foods that raise glucose levels *quickly* have a *high glycemic score*, and are considered unsuitable for blood sugar control. Foods that raise glucose levels *slowly* have a *low glycemic score*, and are considered desirable for blood sugar control. At the very low end of the scale are animal proteins, which contain virtually no carbs. Non-starchy vegetables such as broccoli, leafy greens and zucchini are also low-carb. As one might expect, grains, beans, fruits, and root vegetables (like potatoes and carrots) load the system with easily absorbed sugars, as do concentrated sweeteners.

The problem with the glycemic index is that it’s not scientific. Different databases give radically different advice as to what’s low carb/low glycemic. According to the Official Website of the Glycemic Index and Database (note the authoritative tone implied by the word “official”), “High is 70 and above; medium is 56 to 69; low is 55 and under.”⁸⁷ Not surprisingly, we’re allowed to enjoy grains and noodles. Another website encourages the drinking of wine and beer—even though alcohol is a very rapidly metabolized carbohydrate (which is why people are supposed to drink slowly). One way to make grains and liquor more acceptable is to raise the baseline for a low score. But reassigning starchy foods to the more desirable “low GI” category doesn’t fool the body into assimilating them differently. For many people, foods in even the 30 to 50 range can produce insulin and blood sugar spikes. This is why the more sedate Harvard School of Public Health database states: “In general, a glycemic load of 20 or more is high, 11 to 19 is medium, and 10 or under is low.”⁸⁸ If you liked to eat carbs, which database would you prefer?

Another problem with the glycemic index is that it lacks context. Numerous studies show that blood glucose levels from a food can vary, depending on how the food is cooked or prepared, whether it’s eaten mashed or whole,

Balancing Your Carbohydrates

Not all carbs are bad. While refined carbohydrates cause problems, *some* complex carbohydrates are beneficial. The fiber in seeds, nuts, and vegetables prevents sugars from leaving the small intestine too quickly and overloading the bloodstream. The thyroid and adrenals cannot function properly without some carbohydrate. Along with protein, carbs assist the liver with its detoxification tasks. Carbs help maintain proper hydration of the body, as they directly influence electrolytes and kidney health. A diet too low in carbohydrates may lead to cardiovascular distress. If muscles don’t get enough carbs, they become dehydrated and weak, and can even develop cramps. Physically active people have both a higher need for carbs and an increased ability to metabolize carbs than their inactive counterparts.

Resistant starches—indigestible carbohydrates in green bananas, yams, peas and a few other foods—are now being studied. They aren’t utilized by the body as fuel, but feed the beneficial gut flora and are most beneficial when eaten cold. They should be eaten in moderation by insulin-sensitive people.

The bottom line? When in doubt, eat lots of leafy greens and other non-starchy vegetables.

and whether the targeted food is consumed with fats and proteins (which reduce the GI of the targeted food). These are too many variables for the GI to be of much use! This is why a June 2009 *Journal of Nutritional Science and Vitaminology* article—“Is glycemic index of food a feasible predictor of appetite, hunger, and satiety?”—answered “no!” in response to its title.⁸⁹

In light of this information, one must wonder whose interests these glycemic index databases are serving.

“If It’s Sweet, It Must Be Sugar.” One clue to how the body reacts to sweet substances lies in our *taste receptors*. Both the brain and the gastrointestinal tract (which includes the mouth) contains these receptors. In response to food in the mouth, the body secretes not only digestive enzymes but also *hormones*. One scientist suggests that the hormones, which are secreted into the bloodstream, “may have physiological actions on important functions in the body . . . [which] vary with the site at which the hormones act.”⁹⁰ Some hormones emerge from endocrine-like cells in the lining of the gut, others have been identified in nerves, and still others appear to be located in both the lining of the gut and nerves. Another researcher writes:

[Sugar] is such a potent stimulator of eating in humans and many other animal species. . . . Stimulation of . . . [a given] taste receptor by sugars or artificial sweeteners activates intracellular signaling elements . . . which stimulate peripheral gustatory nerves and, in turn, brain gustatory pathways. The central processing of the sweet taste signal typically activates feeding circuits as well as brain reward systems that promote sweet appetite. Brain autonomic centers may also relay information via the vagus nerve to prepare the digestive system for the incoming carbohydrate-rich food. Digestive and absorptive processing of the ingested food is further coordinated by sugar sensing in the intestinal tract, which modulates nutrient absorption, hormone release, and gastrointestinal motility, and generates satiation signals to the brain that terminate the meal. . . .

The same . . . sweet taste receptor that initiates sugar ingestion in the mouth also detects sugar in the intestinal lumen and triggers physiological responses that promote sugar absorption and metabolism.⁹¹

More simply put, sweet foods stimulate sweet-taste receptors, which promote neurological activity and hormone production. These hormones are responsible for feelings of fullness after a meal. *These responses occur regardless of whether a sugar or an artificial sweetener has*

been ingested, negating any claims that artificial sweeteners don’t stimulate insulin production and are therefore safe. I’ll explore this in detail shortly.

Sucrose / Table Sugar / White Sugar

Sucrose—commonly known as “white sugar” or “table sugar”—is a good starting point for our discussion of sweet tastes because it’s used as the standard against which all other sweeteners are compared. Sucrose is actually a complex molecule made up of equal parts of the simpler “ose” sugars glucose and fructose. It’s broken down in the body by naturally-occurring enzymes. White table sugar is so omnipresent, it seems like a “regular” food. But this purified, white crystalline powder is so highly processed, its manufacture more accurately evokes a chemist’s lab than a cook’s kitchen. White sugar was first derived from sugar cane, and later sugar beets. The majority of sugar beets are now genetically engineered, so the only way to know that your sugar is not made from GMOs is to make sure the label reads, “from sugar cane.”

Sugar cane, which originated in New Guinea, was later brought to Southeast Asia, China, the Pacific and Mediterranean regions, and then other parts of the world. Before a cheap extraction process for sugar was developed, the delights of sugar cane were limited to people who lived in warm climates where it grew. They’d simply cut a piece off the stalk and suck on it. Once people sampled its intoxicating flavor they began to crave it. It was the attempts to satisfy people’s sweet tooth that gave sweet white sugar a very bitter history.

Everything about sugar was labor-intensive and expensive. The plant proved difficult to care for, cane cutting required exhausting manual labor, and the sugar could be extracted only with substantial processing. Plentiful, cheap labor was sought. So in 1512, a slave trade was born when Africans were kidnapped and forcibly brought to the West Indies to work on the sugar plantations. At the beginning of the sugar trade, the largest market for sugar was Europe. At that time, the confection was so expensive that only royalty and the upper classes could afford it. However, once improved methods of extraction were invented, the price of sugar dropped, and common peasants had the privilege of developing almost as many cavities as their wealthier neighbors.

Creating white sugar involves many steps. First the leaves are stripped from the cane. Next, the cane is crushed, liberating the sweet liquid from the inedible fibrous stalk. Then the pulp is boiled several times at high heat to evaporate the liquid and separate it from the sugar crystals. (The dark liquid produced during this phase of manufacturing is sold as *molasses*; see the entry directly

below.) The crystals are then passed through an activated charcoal filtration system to remove what sugar refineries call “impurities”—particles that contain the residual trace minerals. (Half the sugar cane in the US uses activated charcoal made from charred animal bones, which withstand high heat well.) Finally the crystals are bleached with chemicals. So-called “raw” sugar, and the more common brown sugar, receive their light brown color from a tiny bit of molasses mixed back in to the crystals. Sugar made from beets goes through a comparable process.

The vitamins, minerals and enzymes originally in the cane plant are no longer in the white sugar crystals. Regardless of the sugar’s source, it’s transformed from a potentially nourishing plant into uniform crystalline granules with no nutrient content whatsoever. In many ways, eating refined white sugar is like taking a drug. No wonder some writers call sugar “sweet heroin”! Sugar is as different from its original plant as heroin is from poppies.

Molasses

The word *molasses* is related to a Greek word meaning “honey.” Molasses, sometimes also called *treacle*, is the thick syrup produced from boiled sugar cane juice. It was originally considered a byproduct of sugar manufacture. Molasses sold in stores for human consumption is from sugar cane, while beet molasses is considered inedible and is mainly used as animal feed.

There are three grades of molasses: mild, dark, and blackstrap. Mild (the “first” molasses) has been subjected to only one boiling, so it has the highest sugar content. Dark (the “second” molasses), created from a second boiling and sugar extraction, is slightly darker, less sweet, and has a stronger flavor. Blackstrap (the “third” molasses) is from the third boil. Although most of the sucrose from the juice has crystallized (and will be packaged as sugar), blackstrap molasses still has a high sugar content, and most of its calories are from sugar. However, blackstrap molasses does contain significant amounts of iron and a fair amount of manganese, as well as calcium, copper, magnesium, potassium, selenium, and Vitamin B6. Thick, sticky blackstrap molasses is often taken in warm water as a tonic. It has traditionally been added to baked beans and gingerbread, giving them their characteristic flavor.

If young green (immature) sugar cane is used to make molasses, it’s treated with sulfur dioxide—an irritating compound different from naturally occurring sulfur—partly to lighten the color and mostly to eliminate bacteria and molds. This is called *sulfured* molasses. *Un-sulfured* molasses is made from mature sugar cane and doesn’t “need” to be treated with sulfur, probably because there’s enough sugar present in the cane to act as its own

preservative. Many people are allergic or sensitive to sulfured foods, which can cause severe gastrointestinal disorders, respiratory distress, and skin rashes. All molasses is made with sulfur dioxide unless it’s labeled “unsulfured.”

Sorghum molasses is made from various species of the sorghum plant, which is cane-like and also has a high sugar content. This type of molasses is used mostly as cattle feed.

Molasses affects the body in ways similar to refined white cane sugar, although in healthy people its mineral content may mitigate some negative effects of the sugar.

Dehydrated Sugar Cane Juice

Rapadura® and Sucanat® are two brand names of organic, unrefined, unbleached whole cane sugar. The process is simple: sugar cane is squeezed, filtered (to remove plant particles), heated to remove excess water, and then cooled so that grainy brown granules form. The liquid—roughly equivalent to molasses acquired during conventional sugar processing—is not separated from the sugar; so the basic edible (non-fibrous) contents of the sugar cane plant remain intact. The flavor is reminiscent of caramel.

This sugar is comparable, in amounts and uses, to refined white cane sugar. It affects the body similarly.

Maple Syrup

Maple syrup is the boiled, condensed amber sap (literally, plant blood) of sugar maple, black maple and red maple trees. It’s produced only in eastern North America in climates that have cold winters. From late winter to early spring, when the nights are still cold or freezing and the days are a bit warm, holes are drilled into the bark, and buckets or trenches near the trees collect the sap. Maple tree sap is thin, watery, almost tasteless, and very low in sugar. It takes a minimum of 40 gallons of maple sap to produce 1 gallon of pure maple syrup. When manufacturing is complete, maple syrup (and solid maple sugar) contain about 65% sucrose.

To a tree, a hole in its bark is a wound, so it tries to seal it. To prevent the hole from closing and to continue accessing sap, syrup processors usually place formaldehyde tablets in the hole. Although the use of formaldehyde is discouraged today (and in many places, is against the law), fertilizers and pesticides—as well as chemical anti-foaming agents—are still permitted to be used, unless the label states otherwise or the product is certified organic.

What used to be called “Grade A” maple syrup was more refined, contained fewer minerals and had a lighter taste than Grades B or C, which were darker and had more robust flavors. Maple syrup producers now call everything “Grade A” (they don’t want consumers to think that they’re getting inferior syrup), but they do classify them by color and taste.

Maple syrup contains a fairly high amount of manganese, and smaller amounts of zinc, potassium, iron and calcium. All the enzymes present in the raw tree sap are destroyed when the sap is boiled. Not surprisingly, the unboiled, unprocessed sap isn't very sweet, and as it's full of minerals, it's drunk as a tonic in Asia. During maple season, Koreans are known for drinking gallons of raw sap over the course of several days while detoxifying in the sauna.

Maple syrup has a wonderful, distinctive flavor. Cheap supermarket imitations contain no actual maple syrup, but are loaded with corn syrup, artificial flavorings, and chemicals. Maple syrup (not the raw maple sap) affects the body in a way similar to refined white cane sugar.

Coconut Sugar / Coconut Palm Sugar / Palm Sugar / Coconut Nectar (Sap)

To make coconut sugar, nectar from the flower buds of the coconut tree is boiled to evaporate the water. Then it's dehydrated, leaving granules with a taste similar to brown sugar. Coconut sugar, which contains between 70% and 79% sucrose and about 10% each of fructose and glucose, is touted as healthy because of its naturally low fructose content (see details on fructose beginning on page 330).

Palm sugar is derived from the sap of the sugar palm (not the coconut palm), and boiled to concentrate the sweetness. Its taste is similar to that of maple syrup. Coconut and palm sugars are often mistaken for, and used interchangeably with, each other. This makes it difficult for consumers to know exactly what they're getting.

Coconut nectar, readily distinguishable from the other two, is a thick syrup made from coconut tree sap. Proponents assert that it contains live enzymes because it presumably doesn't require intense heating to extract it. Depending on the source, one or more of the sugars is claimed to contain Vitamins B1, B2, B3, B6 and C, as well as potassium, magnesium, zinc and iron. However, these are tiny amounts. The end products are still sugar.

Date Sugar

Dates are 80% sugar. Depending on the kind of date and whether it's fresh or dried, its types, amounts, and ratios of sugars vary. Fresh dates (which are very soft) contain glucose and fructose. Dry dates contain more sucrose.

To make date sugar, the pits are removed from the dates. Then the fruit is dried and ground into fine granules. Date sugar has all the fiber and nutrients of the freshly picked fruit. It's particularly high in potassium, and contains a few trace minerals (not many vitamins). All of its enzymes are intact, as long as the fruit is dried at low enough heat. Date sugar affects the body in a way similar to refined white cane sugar.

Honey

Honey is made by honeybees from nectar that they gather from flowers. The nectar—clear liquid that pools at the end of the flower's female sex glands—is comprised of about 80% water and some complex sugars. After the nectar becomes honey, the nutrient composition is about 80% sugars, 18% water and 2% amino acids, as well as some minerals, vitamins and pollen. On average, fructose comprises 38% of the natural sugars and glucose, 31%; but the ratios are different depending on the honey.

The natural antibiotic properties of honey have been known for centuries, making it popular as both an internal medicine and a skin dressing. Honey contains ample antioxidants, including hydrogen peroxide (H_2O_2). The H_2O_2 is produced by the enzyme glucose oxidase, which is injected into the nectar by the bee during the honey making process. Due to its high sugar content, raw unheated honey pulls out water from bacteria, which dehydrates and kills them. Honey contains enzymes that scavenge pathogenic waste and other debris. It also interferes with the ability of bacteria to produce biofilm, a hard gooeey shelter that protects pathogens. All honeys are easy to digest, and are used in cough syrups because their smooth, thick texture coats and soothes the throat.

To extract nectar from flowers, the bees use their long, tubular tongues like straws. Then they store the nectar in sacs, which function like second stomachs, located in their hind legs. Honeybees must visit between 100 and 1,500 flowers to fill these sacs (which is why they're such valuable pollinators of crops). At optimal capacity, the sacs on each bee hold about 70 mg of nectar, weighing about as much as the bee. Once the sacs are full, the field worker bees return to the hive and pass the nectar to the hive worker bees, who suck the nectar from the sacs. For about 30 minutes, the hive bees chew the nectar, essentially predigesting the fluid. Enzymes from their mouths break up the complex sugars into simpler sugars,

Manuka Honey as Medicine

Of all the honeys, Manuka, from the tea tree flower, contains the highest amount of methylglyoxal (MGO), a natural antibacterial compound. Manuka is highly effective against resistant bacteria, including *Staphylococcus aureus* (which causes respiratory infections) and *Helicobacter pylori* (which causes stomach ulcers). Manuka is commonly applied to wounds, cuts and infections, gargled for sore throats and dental disease, and eaten to eradicate ulcers. It's graded according to its bioactivity: UMF stands for "Unique Manuka Factor." Designations of 12+ to 15+ are usually sufficient for antibacterial properties.

Orthorexia, the New Eating Disorder

A Newly Named Affliction. What happens when you are “too” concerned about the quality of your food? In the United States, thanks to medical doctor Steven Bratman, you now have a new disease: *orthorexia nervosa*. This new “illness” describes undesirable behavior and attitudes that center around food.

Orthorexia Defined. The term *orthorexia nervosa* literally means “correct appetite.” Loosely translated, it means “correct diet.” Even more loosely translated to refer to the general population, it means “the desire to eat healthfully, which is a disease.” Whereas the eating disorders anorexia nervosa and bulimia nervosa pertain to the *quantity* of food consumed, orthorexia pertains to the *quality* of the food.

Bratman’s 2001 book, *Health Food Junkies: Overcoming the Obsession with Healthful Eating*, describes people who have restricted their diets so much that their health has suffered. Bratman himself is familiar with various diets: raw, vegetarian, macrobiotic. When he was younger, Bratman (a self-diagnosed “orthorexic”) rigidly adhered to strict diets on the advice of “food gurus” whom he blindly obeyed. Later as a physician, Bratman was consulted by rigid clients who likewise abused eating. Some couldn’t stop obsessing about food for so many hours, that they could do nothing else. Macrobiotic parents, adhering to what they believed was a rule about limiting water intake, allowed their child only four ounces of water a day—causing the child to become dehydrated. A vegan husband, convinced of his moral correctness, divorced his wife—because she ate meat. And a woman who refused to eat animal protein became deficient in vital amino acids—and, fainting from weakness, crashed the car she was driving and died. In fact, several people died from malnourishment because they insisted on adhering to unrealistic, inflexible theories of eating instead of paying attention to legitimate, but suppressed, messages from their own bodies.

Such extreme behaviors indicate very real and severe emotional problems. The psychological root could be a need to feel in control over one’s life (in any area), a need to feel safe (by controlling food intake), the desire to be “perfect” (by adhering to an unyielding, demanding protocol), or the need to feel special (by eating in ways that are different from the eating habits of most others). Unsurprisingly, rigid individuals often become intolerant of other people’s views about food and health. Convinced that there’s only one correct way to eat (their way), they follow dietary protocols as one would a religion. The diet religion helps one feel holy, superior, and achieve a sense of belonging to a group of people who eat similarly and may tend to proselytize.

A Psychological Analysis. While Bratman correctly observes and justifiably critiques extreme behaviors, the focus on food itself as the disease is misguided. Instead, the underlying emotional issues that are expressing themselves through eating should be addressed. Let us use rape as an analogy. Today, we understand that rape is not related to sex, love or lovemaking. It *is*, however, related to the need to feel powerful by controlling others (and a venting of rage). Similarly, rigid dieting is not related to nutrition or health. It *is*, however, related to the need to feel powerful and seize control because *other* areas of one’s life feel so out of control. *Any* dysfunctional emotion can manifest in many ways, including how (and how much) one eats. Sick and not healthy people consult Bratman, so he has undoubtedly encountered a disproportionately large number of people who abuse food. But what about those who don’t feel a need for his services? Or people whose illnesses have induced them to seek new ways to heal?

A Natural Health Analysis. The creator of this new disease doesn’t always understand (or respect) natural medicine. Ignoring the data on heavy metals and brain dysfunction, he calls people fanatics if they refuse to cook in aluminum pots. He believes that all raw foods aficionados want to escape their bodies because they like the feeling of lightness, not understanding that the high biophoton levels in raw foods may cause one to feel more connected to energy than to matter. And he insists that people with allergies should still try to eat allergenic foods because—remembering how isolated and bad *he* felt when he embraced diets requiring all his focus and time—he worries that allergic persons will harm *themselves* by becoming socially isolated. Plus, he admits, he doesn’t know how to cure allergies.

A Political Analysis. Those who benefit from the invention of “orthorexia” include agribusinesses (which manufacture fake food) and the medical-pharmaceutical cartel (which loves to assign negative labels to people who have normal, justified responses to abnormal situations). Although Bratman’s book was first published in 2001, orthorexia has been widely publicized recently. Are the fake food companies scared by the public’s demand for clean food?

Many products sold to North Americans by Nestlé, General Mills and other conglomerates contain dangerous chemicals, additives, and genetically modified ingredients. But virtually identical products created for export—to Europe, South America, Africa and Asia—are free of these contaminants. The products don’t contain junk because the overseas markets refuse to consume it. People outside the US would laugh if they received a diagnosis of orthorexia!

Meanwhile, the US establishment media refuses to publicize the dangers of what agribusiness tries to foist on the public as “food”—thus supporting attempts to pathologize those who protest the adulteration of our food supply. But despite the food industry’s marketing tactics, the healthy eating movement is gaining momentum. More Americans are trying to eat better, and efforts to persuade people to eat unsafe crap aren’t going well. In the United States, many multinational corporations and the Grocery Manufacturers Association spend millions of dollars trying to defeat proposed laws forbidding the planting of genetically modified crops and requiring that such “foods” be labeled. In some states, the bills were narrowly defeated by only a few hundred votes—and there were unusual delays before the votes were counted. Did someone use that extra time to tamper with the electronic voting machines?

Bratman compares orthorexia to alcoholism and heroin addiction. However, one valid point that he does make—that some people follow rigid diets instead of dealing with their emotions and paying attention to their actual nutritional needs—has been either inadvertently misinterpreted or deliberately distorted. (The sensationalist title of his book doesn’t help.) Now, someone is diagnosed as having orthorexia if she or he:

- ◆ Spends more than three hours a day thinking about healthy food. (What if the person is a professional bodybuilder, meal planner or dietician, or has cancer?)
- ◆ Continually limits the number of foods consumed. (What if the person has food allergies?)
- ◆ Abstains from foods formerly enjoyed. (What if the “formerly enjoyed” food had a negative impact on the person’s health?)
- ◆ Ensures cleanliness of the food by insisting that it be minimally handled and adequately washed. (What if the food is heavily sprayed produce? And does this mean that employees required to wear latex gloves while handling food are orthorexic?)
- ◆ Plans tomorrow’s menu today. (This can include cooks, busy parents organizing meals for their families, someone taking food out of the freezer for the next day—practically everyone.)
- ◆ Refuses to go to a restaurant that doesn’t serve clean or non-allergenic food, and thus becomes socially isolated. (Must “being social” always involve eating?)

Medicine also claims that people are orthorexic if they try to avoid foods containing or contaminated by:

- ◆ Pesticides and herbicides.
- ◆ Genetic modification.
- ◆ Artificial colors, flavors and preservatives.
- ◆ Heavy metals (like arsenic in rice or lead in chocolate).
- ◆ Unhealthy fats, sugars, or added salt.

Some health professionals recognize orthorexia as a mental disorder. The National Eating Disorders Association urges the afflicted to receive treatment—psychotherapy and selective serotonin reuptake inhibitor (SSRI) drugs. The most popular pharmaceuticals are Zoloft®, Prozac®, Luvox®, and Paxil®. The justification for prescribing these drugs is the supposed concern that restricting one’s diet “excessively” can cause anxiety, depression, guilt and shame.

Are most people who want to eat clean food mentally ill? Do they truly have orthorexia? Or is it that over 90% of the food supply in North America is tainted, and people want to be as healthy as possible by eating clean foods? The definition of orthorexia is so vague and all-encompassing that any health-minded individual can be termed neurotic. Mike Adams calls orthorexia “the healthy-eating disorder.” He suggests why the medical establishment attacks healthy eaters:

Increased mental and spiritual awareness is only possible while on a diet of living, natural foods. Eating junk foods keeps you dumbed down and easy to control. . . . It literally messes with your mind, numbing your senses with MSG, aspartame and yeast extract. People who subsist on junk foods are docile and quickly lose the ability to think for themselves. They go along with whatever they’re told by the TV or those in apparent positions of authority, never questioning their actions or what’s really happening in the world around them.

In contrast to that, people who eat health-enhancing natural foods—with all the [naturally occurring] medicinal nutrients still intact—begin to awaken their minds and spirits. Over time, they begin to question the reality around them and they pursue more enlightened explorations of topics like community, nature, ethics, philosophy and the big picture of things that are happening in the world. They become “aware. . . .”⁹²

Food allergies, diabetes, insulin resistance, hypoglycemia, celiac disease, Metabolic Syndrome, and other related conditions are escalating at unprecedented rates. The evidence is irrefutable: these conditions substantially improve, or are eliminated entirely, with a better diet. People who listen to their bodies and feel better by eating a certain way—even if that way seems rigid to those who follow a typical diet of junk—are mentally healthy. They love themselves enough to take good care of themselves.

Let us consider that yet another disease may be developing, one that affects medical personnel in particular. It’s called *in opus ad creare infirmitates*, which means “the need to create illnesses.”

and make the honey less susceptible to bacterial infection during the time it's stored in the hive. The enzymes also help the water in the nectar to evaporate, which thickens the fluid. Finally the bees deposit the nectar into the wax honeycomb hive, continuing the evaporation process by fanning their wings over the nectar. After the nectar has aged and the fluid is thick, the bees seal the comb with more wax to keep the honey clean and free of contaminants. The honey is stored until the bees need to eat it. Honey is the bees' sole source of sustenance during cold weather and food shortages. In one year, the average colony of bees eats between 120 and 200 pounds of honey.

Raw unheated honey, although high in enzymes and some minerals, is so rapidly absorbed into the bloodstream that it can cause extreme drops in blood sugar. With sugar-sensitive people, honey may cause even more severe blood sugar fluctuations than refined white cane sugar. Honey also decays teeth faster than table sugar; there are reports of honey bears with tooth decay! If honey is heated (as in cooking and baking), its nutrients are destroyed.

Some sources warn not to feed honey to infants under one year old, due to possible contamination by spores of *Clostridium botulinum* bacteria. (The bees are presumed to bring the spores to the hive.) *C. botulinum*, which causes infantile botulism, is highly contagious to very young babies due to their lowered immunity and immature digestive tracts. However, I have not seen conclusive proof that honey is to blame for this condition. According to a 1999 Health Canada report, "Random surveys of honey produced in Canada indicate that *C. botulinum* spores are rare. Spores of *C. botulinum* are present in less than 5% of honey and are typically found in very low numbers." Furthermore, only "3 of the 16 infant botulism cases (as of June 1999) reported in Canada since 1979 have been associated with honey."⁹³ A less than 20% chance, over a period of 20 years, hardly constitutes proof to me. Could it be that one isolated report is responsible for the practice of not feeding infants honey? Besides, it's reasonable to assume that the natural antibiotic properties of honey (especially Manuka) would protect against such infection. The susceptible infants may have had exceptionally poor digestion. Were they breast fed? The report doesn't say. A far greater danger to infants than *Clostridium botulinum* spores may be the sudden drop in blood sugar levels that all honey can cause.

In the last several years, almost half of all bee colonies in the United States died. They were killed by a combination of the pesticide glyphosate and electropollution.

Fructose

Fructose is the naturally occurring sugar found in fruit. When in the form of fine crystals, fructose is used like sucrose. However, because fructose is twenty times sweeter than sucrose, less can be used at one time. Fructose, present in many baked goods and condiments, is heavily marketed to the holistic health sector as an alternative to white table sugar. But this is misleading hype, as fructose is a highly refined, synthetic product.

How is fructose obtained? One would think it a simple matter to take apples, berries, peaches or other fruits and extract the fructose from them. However, the process is fairly involved. Just one quick Internet search yielded a whopping 266 patents for fructose *manufacture* (not mere extraction, which apparently isn't possible). The white powder can be produced from many substances, including agave (discussed later). But most fructose is made from corn, a common allergen—and a crop that's almost entirely genetically engineered, at least in the United States. According to one patent, "A process is described for the

production of fructose from glucose. An aqueous solution of glucose is converted to D-glucosone by an enzymatic process. D-glucosone is then converted to substantially pure fructose by chemical hydrogenation. Fructose may be recovered in crystalline form."⁹⁴

"Chemical hydrogenation" sounds a lot more ominous than relatively simple boiling to obtain dehydrated sugar cane juice. Therefore, the harm caused by this synthetic product shouldn't surprise anybody. Like white table sugar (sucrose), crystalline fructose contains no enzymes, vitamins or minerals, which makes it necessary for the body to cannibalize its own micronutrients in order to process the sugar. Even when fructose is ingested in its whole food state, as a component of fruit, some unique problems arise. Health writer Bill Sanda compares the effects of fructose to those of other sugars:

In humans, fructose feeding leads to mineral losses and, especially, higher fecal excretions of iron and magnesium than [does sucrose feeding]. Iron, magnesium, calcium, and zinc balances tended to be more negative during the fructose-feeding period as compared to balances during the sucrose-feeding period. . . . In studies with rats, fructose consistently produces higher kidney calcium concentrations than glucose. Fructose generally induces greater urinary concentrations of phosphorus and magnesium and lowered urinary pH compared with glucose.⁹⁵

Fructose and Uric Acid, Obesity, and Gout

Like all concentrated sweeteners (except for Manuka and a few other honeys), fructose, the sugar in fruit, causes serious health problems. However, it creates other problems as well that are unique. In his book *The Fat Switch*, Dr. Richard Johnson describes the effects of fructose that he learned first from research on animals, and later from research on human beings. Some of these effects may surprise you.

It's well known that before hibernating, animals gorge themselves on food, much of it fruit. Fructose produces ravenous hunger, which makes the animals eat even more. Fructose is not readily available to the cells as energy. Instead, it causes a rise in uric acid levels, which stimulates the body to create fat. However, the uric acid prevents that fat from being used as energy. Instead, the body stores the fat, which lodges in the blood, liver, and fatty tissues. This process is useful and necessary for animals who hibernate—after all, they must live off their fat stores for the entire winter—but it's downright counterproductive for humans who don't have the ability (or desire) to hibernate. The sad truth is, many people who eat fructose don't lose fat quickly, and now we understand why.

To obtain yet another perspective on this special property of fructose, let's compare it to glucose. If the same number of calories of fructose and glucose are ingested, fructose is much more likely to cause weight gain than the glucose. This is because, at the beginning of fructose metabolism, the liver, kidneys and small intestine produce an enzyme called *fructokinase*. Fructokinase catalyzes a cascade of other biochemical reactions, one of which results in the production of yet another enzyme that allows excess uric acid to accumulate. This increase of uric acid, Johnson points out—which *always* accompanies the consumption of fructose—causes a major stress response in both animals and humans.

Excess uric acid in the bloodstream damages the kidneys, even to the point of causing renal failure. Similarly, uric acid inside the cells causes equal harm because it creates free radicals leading to the breakdown of tissue and the accumulation of waste. This disrupts the coenzyme *ATP* (*adenosine triphosphate*), which is responsible for transporting chemical energy within cells for metabolism. Once ATP production is blocked, the *mitochondria*—tiny, independent, energy-producing fuel units on which we depend for vitality and life—malfunction. Then, the following conditions are either exacerbated or caused outright:

- ◆ Excessive hunger
- ◆ Increased fat stores
- ◆ Insulin resistance / metabolic syndrome
- ◆ Diabetes
- ◆ High blood pressure
- ◆ Gout (a type of arthritis)
- ◆ Hyperactive immune response
- ◆ Increased levels of inflammation

A diet containing fructose can quickly create addiction—not only to sweet tastes, but in time, to overeating in general. This is partly due to the disruption of satiety signals reaching the brain. Under normal conditions, *leptin*, a hormone released from fat cells, tells the body to stop eating. However, studies have shown that fructose does not stimulate the release of leptin as effectively as glucose does. Moreover, the leptin that's released from the ingestion of fructose isn't very effective because *fructose also induces the body to become resistant to leptin's messages*. This resistance in part comprises what has become known as "Metabolic Syndrome." People who are already overweight are affected more adversely by fructose than those who are slim or of normal weight.

The rise in the intake of sugar correlates to an alarmingly high upswing in the rates of obesity and diabetes. Research shows that it takes 20 years from the time that sugar (sucrose) is introduced to a culture to see a rise in diabetes. However, startling (and convincing) data on the dangers of eating fructose shows that high amounts will induce similar health problems in only *two weeks*.

Fruit has received a lot of positive press. We are told that fruit is a highly beneficial, nutrient-packed, "fresh from nature," portable alternative to candy, cake, and other sweets. We are exhorted to "eat our fruits and vegetables," as though the two are in the same category—when in truth, they have quite different properties and functions. Especially for people who are ill, fruit's positive reputation is undeserved. It's true that fruit contains minerals, some vitamins, and fiber. And a craving for sweet tastes may have served our ancestors well in times of famine long ago. But in modern times, these cravings can be a curse. Considering the prevalence today of virulent infections and metabolic disturbances—carbohydrate intolerance, Syndrome X, diabetes, and impaired liver function (to mention just a few)—using fructose as a sweetener is downright foolish. Even eating fruit on a regular basis may be compromising one's health.

In addition, Sanda writes, “hypertrophy of the heart and liver” develops in young male experimental animals fed fructose. “Liver, heart and testes exhibit extreme swelling, while the pancreas atrophies, invariably leading to death of the rats before maturity. . . . The females [do] not develop these abnormalities, but they [reabsorb] their litters.”⁹⁶ In other words, the embryos in pregnant females simply dissolve *in utero*.

Fructose actively interferes with copper metabolism, making it impossible for the body to form collagen, a gelatinous substance found in connective tissue, bone, and cartilage. This fructose-induced copper deficiency leads to anemia, blood sugar abnormalities, bone defects, cardiovascular problems (including heart arrhythmia and heart attacks), and infertility. Fructose has also been shown to impair memory in rats. (Fortunately, docosahexaenoic acid—the Omega 3 fatty acid more commonly known as DHA—can help repair neural tissue damage.) People who cannot digest fructose sometimes exhibit symptoms similar to those of lactose intolerance: abdominal cramping, diarrhea or constipation, flatulence, stomach pain, and other gastrointestinal problems.

The uniquely negative properties of fructose are due to how it’s processed in the body. Unlike glucose, which is easily utilized by all the cells, fructose can be metabolized *only* by the liver. But the liver is able to transmute and store only limited quantities. For many people, even a small amount of fructose is too much. With just one glass of fruit juice, state clinical nutritionist Ann Louise Gittleman and colleagues, “the conversion process of fruit into glucose and then into fat can be magnified.”⁹⁷ Such “magnification” can eventually cause fatty deposits and cirrhosis of the liver—similar to problems developed by people who drink too much alcohol. Also in the liver, fructose seizes all the ATP energy stores. (ATP is an acronym for the energy molecule *adenosine triphosphate*.) A loss of ATP makes us feel tired, stressed, and depleted.

Fructose is often marketed as a non-reactive sugar for people with diabetes, based on its reputation of slow release into the bloodstream. But the truth is, blood glucose levels are very erratic if fructose is ingested. Fructose, Sanda emphasizes, “reduces the affinity of insulin for its receptor, which is the hallmark of [one type of] diabetes.”⁹⁸ If glucose cannot enter a cell, it cannot be metabolized, and instead it remains in the blood. To drive the glucose out of the bloodstream and into the tissues, the pancreas secretes even more insulin—and at this point, the body can become insulin-resistant (and thus have a significant elevation of triglyceride levels). This is why journal articles exist with such titles as “Consuming fructose-sweetened, not glucose-sweetened, beverages increases visceral adiposity and lipids and decreases insulin

sensitivity in overweight/obese humans”⁹⁹; “Excessive fructose intake induces the features of metabolic syndrome in healthy adult men: role of uric acid in the hypertensive response”¹⁰⁰; and “A causal role for uric acid in fructose-induced metabolic syndrome.”¹⁰¹ More details of the relationship between fructose and uric acid accumulation is described in the Insert on page 331, “Fructose and Uric Acid, Obesity, and Gout.”

Most people are not informed about the effects of fructose. Among all the sugars, fructose seems to most readily disable one’s ability to feel full. It’s pointless to even consider using fructose crystals as a sweetener, especially when delicious whole fruit is available.

High Fructose Corn Syrup (HFCS)

High fructose corn syrup (HFCS) is a relatively new invention. Until the 1970s, most of our sugar was derived from cane or beets. But HFCS became plentiful and cheap to produce after the US government began subsidizing commercial corn farming. The syrup mixes well, is easy to store, and extends the shelf life of whatever other processed food it’s in. As a result, HFCS is in almost every packaged and prepared food imaginable: bread, cereal, soda, condiments, baked goods, candy, dairy products, canned and bottled vegetables and fruits, sauce, snacks, soup, jam, salad dressings, cough syrup, and even meats.

Unlike standard corn syrup, which is mostly glucose, HFCS is about 45% glucose and 55% fructose. This makes it much sweeter than its counterpart. And, Sanda points out, HFCS “can be manipulated to contain . . . up to 80% fructose and 20% glucose. Thus, with almost twice the fructose, HFCS delivers a double danger compared to sugar [sucrose].”¹⁰² HFCS-90 is 90% pure fructose.

HFCS is manufactured from corn starch. Fermented by three enzymes, the starch is turned into glucose, and then processed to yield high fructose levels. A 2009 *Environmental Health* article showed that almost half the HFCS samples studied were contaminated by mercury.¹⁰³ The corn used in any corn syrup is certain to be genetically engineered. Many people are also allergic to corn. See Sidebar, “Foods and Personal Care Products that Contain Corn Derivatives or Byproducts.”

Industry is now allowed to label HFCS “corn sugar,” “maize syrup,” “fructose syrup,” or simply “fructose.”

Agave Syrup

The agave species—large succulent (water-retaining) plants probably related to the lily—grow in Mexico, in the southern and western United States, and in central and tropical South America. The nectar-producing plants for the burgeoning North American agave syrup market are in Mexico. Their fleshy spiked leaves cover a pineapple-

shaped core that contains a sweet sticky juice. Depending on the species, growing conditions and climate, an agave plant has a lifespan of 8 to 15 years. The leaves of a mature plant are 5 to 8 feet tall, and the plant itself ranges from 7 to 12 feet in diameter.

Agave nectar begins to ferment a few hours after it's taken from the plant. The ancient Mexicans developed a drink made from fermented agave juice, the predecessor of tequila. Modern tequila is made from the blue agave plant.

Most agave syrup consists of about 80% to 95% fructose, with the remainder glucose, depending on the plants providing the syrup and the manufacturing process that is used. Some sellers claim that agave contains inulins, which are naturally occurring polysaccharides (several simple sugars linked together) that are a primary food for intestinal flora. (The gas and bloating that some people experience after ingesting inulin are due to the increase in friendly flora, which digest debris in the intestine.)

Agave dissolves easily in cold liquids, doesn't crystallize like honey, and is sweeter than sugar when used in recipes. Because agave is watery, consumers are advised to use less liquid when baking.

Some brands of agave nectar come in light and dark varieties, like molasses and maple syrup. Darker agave is subjected to less filtering and processing. Lighter is subjected to more. Darker agave, which tastes a bit like molasses, is reported by manufacturers to contain higher concentrations of iron, calcium, potassium, and magnesium. The lighter liquids, which are bland and have almost no taste, are said to contain lower concentrations of minerals. I have not seen the percentages of minerals listed anywhere for any agave product.

Proponents of agave claim that its glycemic index score is lower than that of any other natural sweetener. Agave is marketed as good for people with diabetes, but it contains mostly fructose. Knowing what we do about high fructose levels and body chemistry, it's reasonable to assume that continued use of agave can raise insulin, blood sugar, and triglyceride levels.

How manufacturers describe agave production, and what the patents disclose about its processing, make this fluid seem like two different products. According to manufacturers, agave is made by expressing the juice from the core of the plant, filtering the juice to remove the

Foods and Personal Care Products that Contain Corn Derivatives or Byproducts

People with corn allergies, or who want to avoid GMOs, should not use the following. This is only a partial list.

- ◆ *Ascorbic Acid (Vitamin C)*. Found as a nutrient in nutritional supplements. Most of it is derived from corn.
- ◆ *Inositol and Inosinate*. Found as nutrients in Vitamin B supplements. Extracted from the phytic acid naturally present in the hulls of corn.
- ◆ *Lactic Acid*. Used in some skin care products. From fermented corn starch and sometimes potato starch.
- ◆ *Lecithin*. An emulsifier used in supplements and many food products. Usually from soy, sometimes from corn.
- ◆ *Linoleic Acid*. Used in making soaps, emulsifiers, and oils. From cottonseed, soybean, and other vegetable oils.
- ◆ *Lysine*. Essential amino acid, used in many nutritional supplements. Often derived from corn.
- ◆ *Oleic acid*. Often used in cosmetics. From corn and other vegetable oils.
- ◆ *Pectin*. A gel found in puddings, jams, and other foods. Sometimes derived from corn sugars (dextrose or fructose).
- ◆ *Phospholipids*. Fats that are a major component of cell membranes. Put into nutritional supplements and drugs. Often derived from corn oil.
- ◆ *Phytic Acid*. Indigestible anti-nutrient from the hulls of nuts, seeds and grains, including corn. Inositol and inosinate are extracted from phytic acid and are used as nutrients in nutritional supplements.
- ◆ *Stearic Acid*. Found in fake fats, baked goods, and especially as a binder in nutritional supplements. From corn oil (or cottonseed oil, which is heavily sprayed).
- ◆ *Sugars*. Dextrose, fructose, maltose, dextri-maltose, maltodextrin, cyclodextrin, diacetyl, amylose, amylopectin, invert sugar, isomalt, levulose, monosaccharide, lactate condensation, polyamino sugar condensate, confectioner's sugar. Found in all types of packaged foods, in nutritional supplements, and in pharmaceuticals. Often from corn.
- ◆ *Xanthan Gum*. Used as a food thickener. From corn sugar.
- ◆ *Zein*. Used as a coating for vitamin supplements. From corn protein.
- ◆ *Other substances*: baking powders (some), white vinegar, methanol (rubbing alcohol, poisonous if swallowed), citric acid, caramel, excipients (carriers for the actual ingredients you want to impart), pill binders, malt, monoglycerides and diglycerides (fats that emulsify or blend ingredients), sorbitol, vanilla extract, milo starch.

solids, and then breaking down the carbohydrates in the fluid into sugars through the use of either heat or enzymes. Finally, we're told, the filtered juice becomes concentrated into a syrup that's a little thinner than honey, but sweeter. I have not been able to find information on any agave website about how this final "concentration" takes place. However, the patents provide much more information.

In 1998, a patent was awarded by the United States Patent Office for a process that uses enzymes to transform the more complex agave polyfructose extract into pure fructose. The abstract states:

A pulp of milled agave plant heads are liquified during centrifugation and a polyfructose solution is removed and then concentrated to produce a polyfructose concentrate. Small particulates are removed by centrifugation and/or filtration and colloids are removed using termic coagulation techniques to produce a partially purified polyfructose extract substantially free of suspended solids. The polyfructose extract is treated with activated charcoal and cationic and anionic resins to produce a demineralized, partially hydrolyzed polyfructose extract. This partially hydrolyzed polyfructose extract is then hydrolyzed with inulin enzymes to produce a hydrolyzed fructose extract. Concentration of the fructose extract yields a fructose syrup.¹⁰⁴

The numerous patents for producing agave syrup describe several other ways to obtain pure fructose: bathe the nectar in mineral acids; filter the nectar through membranes; soak minced plant parts in a solution of water and inulase (an enzyme) for a little over a day. (Inulase is an inulin enzyme. Could this be the source of the highly publicized inulin in agave?) Or, collect the minerals and other "impurities" with diatomaceous earth, and then eliminate all the debris by spinning the liquid. (Food grade diatomaceous earth is a safe powder of ground-up fossilized one-celled sea creatures called diatoms. It's commonly dusted on animals for insect control, and if it's food grade, it can be taken internally to dispel parasites.)

Even if you're not a trained chemist, when reading the patents several questions arise. What happens to the viability of the minerals and naturally-occurring enzymes when the nectar is heated at 140°F to 160°F (60°C to 71.1°C)? More to the point, if agave nectar is already so desirable—and because many cheap high fructose sweeteners are already on the market—why go to all the trouble to "purify" the colored, thin, strong-tasting nectar into a final product that's basically nothing more than clear liquid fructose? Might the exotic origin of a tropical

plant induce North Americans to pay high prices for what essentially appears to be glorified high fructose syrup?

Significantly, all the patents I have read rate the final liquid product according to its "purity"—in other words, the amount of processing it has undergone! One site states, "A poor quality fructose syrup has a yellow-brownish color and is *tainted* by the taste and smell of the agave plant." [emphasis added]¹⁰⁵

Health writer John Kohler brings in yet another angle: there is no life in this sweetener, despite claims by some manufacturers that their agave is "raw."

Agave syrup was originally used to make tequila. When agave syrup ferments, it literally turns into tequila. The enzymatic activity therefore *must* be stopped so that the syrup will not turn into tequila in your cupboard. . . . If there is no enzymatic activity, it is certainly not a "live" food.¹⁰⁶

No other sweetener (except raw honey and dates) contains enzymes, either. Let's look at another patent.

It is an object of the present invention to produce a high fructose content syrup through the processing of milled agave plant pulp. . . . to produce a high fructose content syrup [while] the aroma and flavor of the agave plant are removed without undue expense. . . . [and] to produce a concentrated fructose syrup which is stable over time and suitable for human consumption in a wide variety of food and beverages. It is yet another object of the present invention to produce a high fructose content syrup in which the color and flavor may be varied by selection of the combination of processing steps and by variation in the length of individual processing steps.¹⁰⁷

Incredibly, some companies call their product agave *nectar*. This is more than misleading, it's an outright lie. Agave is very far removed from the actual plant.

Xylitol and Other Sugar Alcohols

Sugars ending in "tol" belong to the group of *sugar alcohols* (also known as *polyols*) that are actually carbohydrates, whose chemical structure partly resembles both sugar and alcohol. Some of the more-well known "tol" sugars are xylitol, erythritol, sorbitol, maltitol and mannitol.

Polyols are less sweet than sucrose. They have calories, but the body's inability to metabolize them reduces their caloric count to a negligible .02 to 3.0 calories per gram, as compared to 4 calories per gram for other sugars. The incomplete absorption of polyols also accounts for their lower glycemic index than sucrose or other "ose"

sugars—although as we have seen, a food’s low glycemic index doesn’t indicate safety because the body responds biochemically to any sweet taste as though actual sucrose had been ingested. Polyols do raise blood sugar levels. They also promote electrolyte loss and excessive thirst. Furthermore, the malabsorption in the gut caused by “tol” sugars is severe. If enough polyol is ingested, it causes abdominal cramping, diarrhea, and constipation.

All polyols are processed into refined white powder, but their origins are different. Erythritol is found in fruits, fungi and wine; large quantities are usually manufactured by fermenting plant sugars. Sorbitol and mannitol are made from hydrogen and glucose extracted from corn sugar. As for xylitol, its most common source is the sweet soft center of a (genetically engineered) corn cob, although other sources include plums and various kinds of berries. In Europe and increasingly in the US, birch bark is a popular source because consumers want to avoid genetically engineered corn. Regardless of its source, however, xylitol is manufactured in many steps, and could hardly be considered a whole food. These steps include breaking down the raw materials with either acid or through microbial fermentation—some manufacturers may use GE bacteria—and crystallizing the syrup with ethanol. At some point, xylitol is exposed to a nickel-aluminum alloy to manipulate its molecules via a process called *hydrogenation* (discussed earlier in relation to fats). The toxic chemicals are removed with heating.

Sorbitol and mannitol are widely used polyols that are found in the majority of packaged foods. Like common table sugar, they breed bacteria, including the cavity-causing *Streptococcus mutans*. Over 50% of erythritol is absorbed into the blood but is later excreted in the urine; so it’s touted as having a negligible effect on the digestive tract. Erythritol has 60% to 80% the sweetness of sucrose, and almost no calories.

Xylitol is the most popular of sugar alcohols partly because its sweetness level is close to that of table sugar, and largely due to its reputation as a bacterial deterrent. Proponents state that it’s so slippery, it prevents bacteria from adhering to teeth and other surfaces. For this reason, xylitol is used in gum, candy, toothpaste, mouthwash, and even sinus rinses. Despite xylitol’s positive promotion, however, medical studies are mixed. Xylitol does appear to have modest bacteria-fighting properties for some people, but not to the extent reported by its enthusiasts.

How does xylitol affect gut bacteria? Some researchers claim that xylitol’s slippery properties make it safe even for people with *Candida* overgrowth. Other researchers assert that in the colon, xylitol attracts water and pathogens, causing fermentation and the proliferation of *Candida*

and other harmful fungi. They advise against eating xylitol because it may negatively impact the friendly flora. “Prolonged use or large intake,” Bill Misner advises, “may produce the following side effects: weight gain similar to that associated with high/prolonged sucrose intake, diarrhea, tumor growth, and liver/kidney/brain dysfunction.”¹⁰⁸ Nevertheless, xylitol is heavily marketed to people who have diabetes or want to lose weight.

Unlike humans, dogs absorb xylitol in the intestine and suffer extreme digestive upset, including cramping and diarrhea. If a dog eats a large enough amount of xylitol for its body weight, once the sweetener gets into the dog’s bloodstream it can cause liver failure and sudden drops in blood sugar that may result in seizures and even death. Don’t allow your dog near anything containing xylitol.

Of all the polyols, xylitol may have the most redeeming qualities due to its ability to combat pathogens. However, the fact remains that because xylitol can’t be completely digested, it may cause moderate to severe gastrointestinal cramping for most people, especially if eaten in large amounts. If you want to use it as a sweetener, begin with small amounts and monitor its effects. That said, some people who cannot manage other types of sugars appear to tolerate xylitol. As always, let your experience guide you.

Saccharine

Saccharine was the first artificial sweetener on the market. Derived from coal tar, it was ultimately acknowledged as carcinogenic and destructive to the beneficial gut flora. At different times, it has been banned (and sometimes reinstated) in various countries.

Saccharine causes weight gain, despite claims that fake sweeteners are ideal sugar substitutes for people who want to lose weight or who have diabetes. A 2008 article—“A Role for Sweet Taste: Calorie Predictive Relations in Energy Regulation by Rats”¹⁰⁹—described three experiments using saccharine. Rats who ate lower-calorie, artificially sweetened yogurt had more weight gain, more body fat, and a more severely impaired ability to stop eating than rats who ate higher-calorie, glucose-sweetened yogurt. The saccharin-sweetened foods interfered with the rats’ normal biochemistry. In another study using two groups of rats, the first group was given high-calorie sugar drinks and the second group was given drinks infused with saccharin. After ten days, both groups were given a high-calorie, sweet snack. The rats that had consumed artificial sweetener in their drinks ate *three times* more calories than the rats that had not consumed artificial sweeteners. The scientists concluded that artificial sweeteners prevent the body from discerning what its caloric intake actually is, which leads to overeating.

Aspartame

In the first chapter, I discussed how aspartame was created, who kept it on the market, and many of its harmful effects, which include gastrointestinal and respiratory problems, migraines, heart palpitations and seizures. However, aspartame also affects people in ways similar to saccharine. Medical doctor James Bowen explains the biochemical mechanism by which aspartame causes hunger:

The reason aspartame so strikingly stimulates the appetite is it provides over half of its content in a form of a phenylalanine isolate.

The amino acid phenylalanine outcompetes all the others at enzyme sites in the body. This suppresses the formation of dopamine from tyrosine and the formation of serotonin from tryptophan. The serotonin is the neurotransmitter that reports carbohydrate metabolism. When your serotonin levels are not allowed to [rise] as they normally do when you eat carbohydrates, you crave more and more food. The dopamine is the neurotransmitter that lets you feel satisfied, so when you use aspartame you have unsatisfiable cravings. The aspartame also poisons your metabolism so you cannot burn calories.¹¹⁰

This is the first time in human history that we have encountered various substances that look, smell and taste like food—but that fail to deliver what they promise. The body “expects” to receive considerable calories when it encounters an artificial sweetener. When these calories are not forthcoming, the body will seek them out—in the form of calorie-laden food. In 2005, at the American Diabetes Association’s 65th Annual Scientific Sessions, Sharon P. Fowler reported the results of reviewing 25 years of data. For every diet soda people drank each day, there was at least a 65% chance that they would become overweight or obese during the next seven to eight years. (Someone who is 20% over their ideal weight is obese.)

Sucralose

Manufactured under the trade name Splenda®, sucralose has captured a sizeable part of the artificial sweetener market that was formerly filled by aspartame, and to date is in over 4,500 food and beverage products.

Sucralose was discovered in the mid-1970s by a researcher from India who was working with corporate scientists in London. When a colleague asked him to test the chemical, he misunderstood and thought he had been asked to *taste* it. The substance tasted very sweet; in fact, it’s 600 times sweeter than sucrose. The compound was

sucralose; the chemical name was chlorinated hydrogen. What began as a misunderstanding of instructions became the highly lucrative artificial sweetener Splenda®.

Only two human trials on sucralose were published by 2006, but the FDA approved sucralose for human consumption anyway. A mere 36 subjects were used for those two trials, the longest of which lasted only four days—a test for the effects of sucralose on tooth decay. Research revealing up to 40% shrinkage of the thymus gland, and liver and kidney enlargement, wasn’t considered important enough by the FDA to delay or refuse approval.

Although Splenda® is marketed to people who want to balance their blood sugar and lose weight, the product helps neither. Other ingredients in Splenda®, in addition to sucralose, are the simple sugars maltodextrine and dextrose, which are caloric. They’re used as fillers because the amount of sucralose that provides intense sweetness is so minuscule. The sucralose in the mix, however, is much more problematic. As it turns out, it’s absorbed in the fat cells. It reduces beneficial gut bacteria by 50%. And it’s made from chlorine. The “people’s chemist” reports:

When used with carbon, the chlorine atom in sucralose forms a “covalent” bond. . . . Unlike ionic bonds [such as in sodium chloride, or table salt], *covalently bound* chlorines [are highly dangerous to] . . . the human body. They yield insecticides, pesticides, and herbicides. . . . It’s therefore no surprise that the originators of sucralose, chemists Hough and Phadnis, were attempting to design new insecticides when they discovered it! It wasn’t until the young Phadnis accidentally tasted his new “insecticide” that he learned it was sweet. And because sugars are more profitable than insecticides, the whole insecticide idea got canned and a new sweetener called Splenda® got packaged.

To hide its origin, Splenda® pushers assert that sucralose is “made from sugar so it tastes like sugar.” Sucralose is as close to sugar as Windex® [a glass cleaning detergent] is to ocean water.¹¹¹

Dr. Bowen further explains the chemistry of sucralose.

Splenda®/sucralose is simply chlorinated sugar; a chlorocarbon. Common chlorocarbons include carbon tetrachloride, trichlorethylene and methylene chloride, all deadly. Chlorine is nature’s Doberman attack dog, a highly excitable, ferocious atomic element employed as a biocide in bleach, disinfectants, insecticide, poison gas [during World War I] and hydrochloric acid.

Concerning the Use of Products Containing Aspartame (NutraSweet®) by Persons with Diabetes and Hypoglycemia

On August 9, 1994, medical doctor and diabetes specialist H.J. Roberts published a report on the link of aspartame to diabetes and hypoglycemia. The report basically stated that aspartame reacts harmfully with insulin and can actually cause, if not hasten, the onset of diabetes. Dr. Roberts had been a member of the American Diabetes Association for 35 years. Although his report was rejected by the ADA, it was published in a prestigious medical journal. The doctor wrote:

I have treated many patients with diabetes mellitus and hypoglycemia (low blood sugar) in my capacity as a Board-certified internist and an endocrinologist. . . . Since both groups should abstain from sugar, I initially rejoiced that these persons had an acceptable and presumable safe sugar substitute in aspartame. Unfortunately, many patients in my practice, and others seen in consultation, developed serious metabolic, neurologic and other complications that could be specifically attributed to using aspartame products. This was evidenced by:

- ◆ The loss of diabetic control, the intensification of hypoglycemia, the occurrence of presumed insulin reactions (including convulsions) that proved to be aspartame reactions, and the precipitation, aggravation or simulation of diabetic complications (especially impaired vision and neuropathy) while using these products.
- ◆ Dramatic improvement of such features after avoiding aspartame, *and* the prompt predictable recurrence of these problems when the patient resumed aspartame products, knowingly or inadvertently. I have cited many instances of severe complications in patients with diabetes and hypoglycemia caused by the use of aspartame products in my books and scientific articles. . . .

I now advise *all* my patients with diabetes and hypoglycemia to avoid aspartame products. A number of alternatives are available. I regret the failure of other physicians and the American Diabetes Association (ADA) to sound appropriate warnings to patients and consumers based on these repeated findings. . . . Indeed, the ADA (of which I have been a member for over three decades) even refused to print an abstract of adverse reactions I encountered in 58 diabetic patients that was submitted for its 1987 annual meeting. This abstract subsequently appeared in *Clinical Research* (Vol. 3: 489A, 1988).

The AMA, the FDA, and the ADA dogmatically continue to express the unequivocal opinion that aspartame is completely safe for diabetics—and nearly everyone else.

I have discussed some of the reasons aspartame might aggravate diabetes and hypoglycemia in [my] books. The possible mechanisms include the following:

- ◆ Marked changes in appetite and weight as reflected by paradoxical weight gain or severe loss of weight.
- ◆ Excessive insulin secretion and depletion of the insulin reserve.
- ◆ Possible alteration of cellular receptor sites for insulin, with ensuing insulin resistance.
- ◆ Neurotransmitter alterations within the brain and peripheral nerves.
- ◆ The toxicity of each of the three components of aspartame (phenylalanine, aspartic acid, and methylester, which promptly becomes methyl alcohol or methanol), and their multiple breakdown products after exposure to heat or during prolonged storage.

I have asserted in my publications, and in testimony both to Congress and FDA advisory group, that the current wholesale ingestion of aspartame products by over half the adult population constitutes an imminent public health hazard. Yet, this warning continues to be ignored by the medical profession and the FDA.

In addition to patients with diabetes and hypoglycemia, [people at risk] include pregnant women, children, patients with epilepsy, liver [disease], kidney disease and eating disorders, older persons with memory impairment, and the relatives of aspartame reactors, diabetics and patients with phenylketonuria.

Many also correctly ask: Why is aspartame still on the market? Their concern is intensified by the high incidence of brain tumors in animals (known before FDA approval), and the reasonable doubt I have documented about the apparent contributory role of aspartame in human brain tumors.

by Persons with Diabetes and Hypoglycemia," August 9, 1994

Artificial sweeteners have long been promoted as weight reducing aids. But research from as early as 1986 has shown that these products cause the very diseases they are claimed to prevent! All artificial sweeteners (including saccharine, aspartame, sucralose and neotame) trigger harmful biochemical changes by lowering levels of beneficial gut flora, raising levels of harmful gut flora, boosting appetite, disrupting metabolism, and impairing the body's ability to handle glucose—thus causing obesity.

This data has appeared in many publications, including:

Sucralose is a molecule of sugar chemically manipulated to surrender three hydroxyl groups (hydrogen + oxygen) and replace them with three chlorine atoms. Natural sugar is a hydrocarbon built around 12 carbon atoms. When turned into Splenda® it becomes a chlorocarbon, in the family of Chlorodane [also called Chlordane, banned by the EPA in 1983 for all uses except termite control], Lindane and DDT.

It is logical to ask why table salt, which also contains chlorine, is safe while Splenda®/sucralose is toxic? Because salt isn't a chlorocarbon. When molecular chemistry binds sodium to chlorine to make salt, carbon isn't included. Sucralose and salt are as different as oil and water.

Unlike sodium chloride, chlorocarbons are never nutritionally compatible . . . and are wholly incompatible with normal human metabolic functioning. . . . Chlorocarbons such as sucralose deliver chlorine directly into our cells through normal metabolism. This [is what] makes them effective insecticides and preservatives.¹¹²

Users have experienced, and researchers have observed, the following effects from ingesting Splenda®:

- ◆ Eye problems: spots in vision, cataracts.
- ◆ Gastrointestinal disorders (bloating, constipation and diarrhea, cramps, nausea, and vomiting).
- ◆ Joint pain, especially in the knees.

- ◆ Neurological problems (anxiety and panic, concentration difficulties, depression, faintness, migraines, seizures).
- ◆ Skin problems (rash, burning, itching, welts, blisters).
- ◆ Enlarged liver and kidneys (which also become calcified).
- ◆ Degenerated adrenals.
- ◆ Shrunken ovaries and thymus.
- ◆ Abnormal decreases in numbers of red blood cells, thyroxin levels, urination levels, and minerals.

You may have wisely given up aspartame, but do you really want to use sucralose instead?

Stevia

Botanically, stevia is part of an entire genus (a plant classification) of about 150 species of herbs and shrubs that are native to South America and Central America. The species *Stevia rebaudiana* Bertoni—known in Paraguay as *Ka'á he'en*, or *sweet leaf*, and simply called “stevia” by Westerners—is a two-foot-high tropical shrub with small leaves. When commercially grown, the plant needs careful attention, as it can be difficult to cultivate seeds that germinate. Much of the commercial stevia crop is obtained from cuttings. Stevia has no calories, has a low glycemic index (for what that's worth), and its extract is up to 300 times sweeter than sucrose. It's also stable when heated to 388°F or 198°C (although some sources say it can tolerate heat up to 392°F or 200°C). For over 1,500 years, various tribes in Paraguay, Brazil and elsewhere have been using different species of the plant not only as a sweetener, but also as a tea to treat heartburn and other conditions, and to balance blood sugar levels.

Stevia became introduced to non-native peoples after scientist Moisés Santiago Bertoni (1857–1929) emigrated from the Italian section of Switzerland, where he was born, and eventually settled in Paraguay. While researching the ethnography and language of the Guaraní Indians (along with his regular studies of botany, zoology, agriculture, biology and meteorology), he was introduced to the plant. In a 1918 edition of a Paraguayan journal, Dr. Bertoni discussed experiments showing that stevia not only was safe, but also that it promoted health. The chemist conducting the experiments, a Paraguayan source points out, was none other than Bertoni's wife, “Eugenia Rebaud Bertoni, with whom he shared the discovery. . . . In the scientific name of the plant, . . . the maiden name of his wife also appears.”¹¹³ In 1931, two French chemists further isolated the glycosides (botanical compounds) that give the herb its sweet taste, and named them *stevioside* and *rebaudioside*.

The results of an extensive Internet literature search, posted at cookingwithstevia.com/petition.html, is accompanied by an explanation of who had written the early articles on stevia, which has a noble history.

Articles published in scientific journals documenting the safe use of stevia [many published in Spanish and Portuguese] . . . were written by botanists, chemists, and food technologists who are experts qualified by training and experience. Over 120 articles about stevia were written prior to 1958 [and some, written over 100 years ago]. Most of the articles are written by scientists or government officials. Only three of the 120 articles referred to were written by or published for the lay public. All were published in journals and books. Several more articles written after 1958 reviewed the use of stevia as food prior to 1958. Over 900 articles have been published on stevia to date.

Some of the articles written about stevia were funded by the United States Government. Letters on file at USDA chronicle the fact that the US government had samples of stevia leaf and intended to investigate it as a crop for the USA as early as 1921. Articles written by American scholars and published in American journals prior to 1958 clearly state stevia leaf has been used in Paraguay for many years and that no adverse effects have ever been reported from the consumption of stevia leaf.¹¹⁴

Outside the US, stevia was becoming widely used in countries that preferred something stable and safe instead of the artificial sweeteners saccharin and cyclamate, which were known to be carcinogenic. Japan, which first produced stevia as a commercial sweetener in 1971, was using 40% of the world's stevia for packaged foods, soda, and table use. Stevia was also becoming popular in other parts of Asia, in Israel, and of course in South America.

In the US, it was a different story. Despite centuries of stevia's safe use, in 1991 the FDA banned it, conducting search and seizure raids against companies that sold it. The reason for the ban, said the FDA, was that stevia was an unsafe food additive. Nevertheless, in 1995 the agency allowed stevia to be sold as a dietary supplement though not as a sweetener. With typical convoluted logic, in 2008 the FDA permitted stevia to be used in processed, packaged foods and drinks as long as companies did not call it a "sweetener" or refer to it as sweet—otherwise, stevia would be regarded as an unsafe food additive under certain legal conditions as defined by the FDA.

The legal status of stevia worldwide keeps changing: It's illegal as a sweetener but legal as a dietary supplement; it's not permitted for humans but can be added to animal feed; etc. Check the laws in your country.

A petition had been submitted to the FDA in 1995 that cited over 900 studies on stevia, none of which showed a lack of safety. Here is just a small sample of research on stevia, from over 60 years ago to the present:

- ◆ In 1954, an article called "Stevioside: A Unique Sweetening Agent," written by a researcher at the Heriot-Watt College in Edinburgh, Scotland, appeared in *Chemistry and Industry*.¹¹⁵
- ◆ In 1986, a study published in the *Brazilian Journal of Medical and Biological Research* described stevia's ability to significantly improve glucose tolerance.¹¹⁶
- ◆ In 1997, three Venezuelan chemists were reported to identify, for the first time, antifungal and antiviral effects in some of stevia's compounds. More recent research has confirmed some of this.^{117, 118, 119, 120}
- ◆ In 2004, researchers in Eastern Europe published an article called "Glucose concentration in the blood of intact and alloxan-treated mice after pretreatment with commercial preparations of *Stevia rebaudiana* (Bertoni)." One group of mice was fed stevia, another group was fed stevioside, and a control group was fed neither. All the mice were then given alloxan to induce diabetes. (You may recall that alloxan is a compound commonly found in white bread; see page 312.) The scientists reported: "Pretreatment with stevia, and to a greater extent with stevioside, protected test animals from the toxic action of alloxan compared with controls."¹²¹
- ◆ Numerous studies show that stevia may not only enhance insulin *secretion*, but it may also enhance insulin *utilization*. In 2005, an article called "Increase of insulin sensitivity by stevioside in fructose-rich chow-fed rats," concluded that stevioside, taken orally, improved insulin sensitivity, and seemed indicated for either people with diabetes, or for those who consumed large amounts of fructose.¹²²
- ◆ The title of a 2013 article in *Journal of Diabetes Complications*, "Antioxidant, anti-diabetic and renal protective properties of *Stevia rebaudiana*," summarizes what the researchers found.¹²³

Some studies have shown that stevia contains natural antioxidants. It doesn't appear to be allergenic and it doesn't cause cavities. The compounds that give stevia its sweet taste pass through the digestive tract

without chemically breaking down, although a small amount of some *metabolites*—byproducts of the original compounds—are absorbed by the gut. The metabolites that are absorbed (such as steviol, from stevioside), are further transformed by the body and excreted in the urine, undetectable in the blood. Stevioside lowers blood glucose levels and blood pressure. Many studies done on animals have shown that stevia has often been found to possess antifungal, antibacterial, and antiviral properties (it prevents viruses from attaching to cell membranes).

Despite these glowing reports, stevia does have issues. Like other sweeteners, its intensely sweet taste without any accompanying calories may trigger insulin, glucose and leptin spikes in susceptible people. Normally, insulin levels rise in response to more glucose in the blood, to push the glucose into the cells. But if there's simply a sweet taste without any glucose present, adrenaline and cortisol levels will rise to mobilize sugar from other sources such as the liver. A constant outpouring of adrenal hormones eventually results in adrenal damage. This would explain why an insulin-resistant, carbohydrate-addicted friend of mine reports getting very hungry every time he eats stevia. So, despite the studies reporting increased insulin utilization, the mere sweet taste of stevia could cause the opposite reaction in some sensitive people.

Perhaps the tolerance (or intolerance) to stevia depends on what form of the herb is being used. Many companies, eager to cash in on this new “miracle sweetener,” are making stevia readily available in liquids and powders of various colors and even flavors! But they aren't telling consumers the truth about how the herb is processed. As with any other food, processing is the key to how the ingredients behave.

The clue to how stevia works can be found only in the whole herb. The plant *is* sweet. But its sweetness is not comparable to that of sucrose, honey, maple sugar, polyols, or molasses. The taste of whole stevia leaf lingers in the mouth longer than most sugars, and the plant has an aftertaste that some describe as bitter and others describe as licorice-like. Stevia's aftertaste is due to the presence of high amounts of stevioside. It's rebaudioside (the other glycoside) that's responsible for the plant's intense sweetness.

Again, a search of the US Patent Office yields valuable clues. Numerous patents exist (one awarded in 1973) not only for the *extraction* of stevia, but also for *processing* methods. Most of the patents are for ways to substantially decrease the levels of bitter stevioside and increase the levels of sweet rebaudioside. These methods range from manual cross-pollination of selected seed-bearing plants to obtain the desirable characteristics, to sophisticated manipulation in the laboratory. Some companies treat

the plant with enzymes to eliminate the stevioside so that only the rebaudioside remains. One patent, issued October 5, 1999, outlines an intricate separation of the various components to yield only the very sweet glycoside rebaudioside-A. This method involves extraction, dissolving the mixed sweet glycosides with methanol solvents, cooling, concentrating, filtering through resin, and spray drying to obtain a crystalline solid “of desired purity.”¹²⁴ Does this “pure” white powder sound like anything else? This kind of rigorous processing is far enough removed from the simple drying and powdering of the plant to require—and receive—a patent.

In the US, stevia is available as a greenish brown powder, greenish brown liquid, white powder, and clear liquid. The green powder is simply the whole dried leaves ground to a powder and the green liquid is a tincture made from the dried green herb. Any other product is a laboratory-synthesized chemical. White stevia products may be regarded as synthetic sweeteners, as they contain only selected portions of the plant that the manufacturer has decided are important. In addition, almost all of the white stevia liquids and powders on the market are bleached, and some contain preservatives.

It's not surprising that the modified extracts are very different from the whole leaf or whole powdered herb. Extracts taste similar to the ubiquitous table sugar, and lack the herb's full range of health-promoting effects. All of a plant's compounds tend to interact with each other in beneficial ways, not all of which are necessarily known.

A stevia company representative once told me that he, too, doubted that a *partial extract* would have the healing properties of the whole plant. He told me how to obtain good stevia and how to use the whole herb optimally. To growers: Harvest it once, before the blossoms open—multiple pickings will yield bitter leaves. The stems and the ribs of leaves, as well as the leaves themselves, contain sweet glycosides, so don't throw out any part of the leaf. To consumers: Stevia can add only a certain amount of sweetness. Use small amounts; more isn't better. Large amounts may taste bitter and not sweet. If you do buy white stevia extract, make sure it's processed with water and not solvents. Removal of coloring should be done with high pressure filtration and not bleaching. You can tell that a stevia extract has been filtered by putting it in some water, which adds back a slight bit of color.

The company rep also told me that stevia appears to even out blood sugar levels by eliminating both the spikes and drops. Health professionals who have monitored clients using his stevia found that it was particularly potent when taken with the herb *Gymnema sylvestre* (also called

shardunika); the two herbs act synergistically to normalize blood sugar levels. Many people, in fact, report that stevia seems to enhance the effects of other herbs, whether used in herbal teas, tinctures, or in cooking and baking.

There's an obvious chemical difference between a whole plant (or its whole extracts) and isolated compounds of that plant. Therefore, the clear extracts and white powders of stevia may not only lack essential components. Long term, they might be creating an imbalance due to the removal of important components. This will be addressed in more detail later, in the **Herbs** section.

Not-So-Sweet Summary

I have devoted considerable space to sweeteners because they have such an enormous impact on our well-being. "In the last twenty years," writes Bill Misner, "we have increased sugar consumption in the USA [from] 26 pounds to 135 [pounds] of sugar per person per year! Prior to . . . 1890 . . . the average consumption was only 5 pounds per person per year! Cardiovascular disease and cancer was virtually unknown in the early 1900s."¹²⁵ The food industry, attempting to bypass the long recognized problems of cavities and blood sugar disruption resulting from excessive sugar consumption, keeps synthesizing new "improved" artificial sweeteners that are far more harmful than concentrated "natural" sweeteners. There is no valid reason to use them, ever.

As for so-called natural sweeteners, most of them are at least a couple of steps removed from their original state because they must be concentrated to accentuate their sweetness, and the heat required to concentrate them changes some of their basic characteristics. Healthy people can generally handle moderate amounts of natural sweeteners. Those whose health issues are not too severe may tolerate them sometimes. But those who are very ill would be wise to avoid them altogether.

If your adrenals, pancreas and liver are functioning properly and you still crave sugar, the craving may be due to certain foods in the diet that are causing brain chemical imbalances: the wrong types of fats, grains (even if properly prepared), or inadequate or excessive amounts of animal protein. You could be lacking essential minerals. Or you might be harboring *Candida albicans* or other pathogens, all of which thrive on sugar. If you find that sweet tastes stimulate a cascade of undesirable biochemical reactions, no matter what you're using, stop eating it! Quelling a sweet tooth can go a long way toward helping you feel better. If you are addicted to sugar and can't quit, please consult a health practitioner with a solid background in biochemistry and nutrition. It may restore your health and even save your life.

Synthetic Chemicals and Fake "Foods"

There's an entire category of fake foods that transforms the *art and science of farming* into the *industry of food*. Among these imposters are imitation "cheese" and texturized vegetable protein (TVP) made from soybean isolates subjected to abnormally high heat; and margarine made from vegetable fats whose molecules are artificially manipulated in ways that don't naturally exist.

Most ingredients that are isolated from their original matrix and radically altered through chemical processes or heat are not only hard to digest, but they have little or no nutritional value. Nutrient-dense food is loaded with flavor, while fake, devitalized ingredients we call "food" are tasteless. It's counterintuitive to deplete the soil with synthetic fertilizers, pesticides and herbicides; raise animals in crowded environments on foods they don't normally eat; raise crops on tired, substandard soil—and then process these "foods" with loads of sugar, salt, and artificial flavorings to make them taste like their more natural counterparts. There is no "need" to enhance food with dangerous chemicals if we grow plants the way they're supposed to be grown and raise animals the way they're supposed to be raised. Real food is delicious. At most, we might want to season our meals with healthy oils, genuine salt, herbs, and spices.

Below are a few ways in which we disguise and alter foods to make them taste better than they really are, and look better than they appeared after they were processed.

Preservatives, Dyes, Fragrances, and Flavorings

So-called natural fragrances and flavors are used in foods as well as cleaners, cosmetics, drugs and skin care items, even if they were never even intended to be edible. Of the over 3,000 additives for foods, half are synthetic flavorings. The majority of flavorings, dyes, and so-called preservatives are manufactured from petroleum. Their contents are legally protected as "trade secrets."

"Trade secrets (as defined by FDA) and the ingredients of flavors and fragrances do not have to be specifically listed," says an *FDA Consumer* article.¹²⁶ Even if the label reads "contains natural flavors," the flavors are legally allowed to be adulterated or comprised entirely of synthetic chemicals. Synthetic fragrances can consist of up to 5,000 hydrocarbons (derived from petroleum or natural gas), and as many as 200 other ingredients, which instead of being listed separately can simply state "fragrance." Petroleum, natural gas, and their derivatives are not compatible with living systems, but food companies try hard to convince the public that fake foods are innovations rather than atrocities.

Among other conditions, these synthetic flavorings and fragrances cause cardiac and immune disorders, allergic reactions, digestive disturbances, and damage to the central nervous system, respiratory tract, liver, and kidneys. They are even causal factors in cancer.

Artificial preservatives tend to be carcinogenic. BHA (butylated hydroxyanisole) and BHT (butylated hydroxytoluene), commonly added to oils to delay deterioration, have also been found to damage the kidneys, liver, and nervous system. Sodium nitrate and nitrite, often added to processed meats to prevent bacterial growth, transform into carcinogenic nitrosamines in the stomach.

They cause neurological damage as well as more gastrointestinal distress. The pink color of nitrate and nitrite treated meats may deceive the consumer into believing that the meat is fresh and wholesome when it's not.

One chemical commonly used as a "flavor enhancer" is monosodium glutamate, abbreviated MSG. A poison that in some ways mimics the action of toxic metals, MSG can cause abnormal blood pressure, muscle and joint pain, gastrointestinal and respiratory difficulties, skin rashes, and blurred vision. But MSG is mainly a neurotoxin. Like aspartame, it impairs the function of the brain and nervous system, leading to various mental, emotional, and motor symptoms that include depression, dizziness, migraines, seizures, loss of balance, insomnia, hyperactivity in children, mental confusion, and anxiety. Sometimes MSG poisoning is misdiagnosed as Alzheimer's or Amyotrophic Lateral Sclerosis (also known as Lou Gehrig's disease).

Glutamate (like aspartame) is especially insidious because it can cross the delicate blood-brain barrier, which is a network of tightly packed, specialized capillaries designed to keep dangerous substances from entering the brain. Furthermore, glutamate can force the blood-brain barrier to *remain open*, which allows other harmful agents to enter.

Although MSG is ubiquitous and is used worldwide, this doesn't mean it's safe. *Excitotoxins: The Taste that Kills*, by neurosurgeon Russell Blaylock, describes in detail how and why MSG causes so much harm, and what people can do to minimize or repair the damage. He also provides the many chemical names and forms of MSG—which is important, as many items are legally allowed to contain MSG without having to be labeled as such. See Insert, "The Truth about MSG," for a guide to the chemical names of MSG and what foods contain it.

In case you thought that MSG was the ultimate triumph in food additives, the article drolly titled "Better Disguises through Chemistry" discusses the invention of yet a newer chemical. This chemical:

tricks the taste buds into sensing sugar or salt even when it is not there. Kraft Foods, Nestlé, Coca-Cola and Campbell Soup are all working with a biotechnology company called Senomyx®, which has developed several chemicals, most of which do not have any flavor of their own but instead work by activating or blocking receptors in the mouth that are responsible for taste. They can enhance or replicate the taste of sugar, salt and monosodium glutamate, or MSG, in foods. . . .

While food safety experts applaud efforts to reduce salt, MSG and sugar, they expressed concerns about the new chemicals, saying that more testing needed to be done before these were sold in food. [Nonetheless] since Senomyx®'s flavor compounds will be used in small proportions

(less than one part per million), the company is able to bypass the lengthy FDA approval process required to get food additives on the market.¹²⁷

McDonald's Head Launches National Diabetes Week

Bill Glasson, the president of the Australian Medical Association, has described inviting the head of McDonald's to launch National Diabetes Week as like "inviting Dracula to the opening of a blood bank."

—News in Brief
British Medical Journal, July 17, 2004

In obtaining *GRAS* (Generally Recognized As Safe) status for this new additive, Senomyx® tested the chemical for less than 18 months. A main study used to determine the chemical's safety was a 3-month trial using rats. The executive director of the Center for Science in the Public Interest (this was before the organization was co-opted by Big Pharma) expressed strong reservations about this protocol: "A 3-month study is completely inadequate. What you want is at least a 2-year study on several species of animals." Unlike other chemical compounds that are listed individually as ingredients, Senomyx® is "lumped into a broad category—'artificial flavors'—already found on most packaged food labels."¹²⁸ The company that created this new chemical was awarded at least five patents.

Packaged foods almost always contain dangerous preservatives to extend their shelf life. There's no reason to use these chemicals to preserve food when more biocompatible substances can safely and effectively be used instead. Just three are Vitamin E tocopherols, ascorbic acid (commonly called Vitamin C), and rosemary essential oil. Fermenting and drying, practiced for countless centuries, are other options.

The Truth About MSG

Conditions and Diseases

What is the flavoring that makes you crave more of whatever it is that you're eating? It's not the food—it's the chemical *monosodium glutamate*, or *MSG*.

For decades worldwide, MSG has been used by scientists to create obese mice and rats used for studies on diet and diabetes. Rats and mice are not naturally obese, so when they're born, scientists have to inject them with MSG—which triples the amount of insulin the pancreas creates—to make the animals fat. The "MSG-treated rats," as the scientists call them, are not the only ones to become obese. So do humans, because MSG appears in almost every manufactured food.

All protein is comprised of amino acids. Glutamic acid, which is an amino acid, is present in protein in its *bound* state. The minute amounts of free glutamic acid in some unadulterated proteins (such as seaweeds) are not enough to induce a reaction. However, monosodium glutamate (MSG) is actually *free glutamic acid* that is released in foods through processing. When large amounts of glutamic acid (along with other manufacturing contaminants) are released from processed protein, people eating the food may react negatively to even tiny amounts, either immediately after ingestion or up to 48 hours later. About 30% of the United States population experiences adverse reactions when fed MSG. In their Registry of Toxic Effects of Chemical Substances, The Centers for Disease Control call monosodium glutamate a *mutagen* and a *reproductive effector*.

MSG causes problems in many areas.

- ◆ Endocrine dysfunction: obesity, reproductive disorders, and diabetes.
- ◆ Heart problems: angina, cardiac arrhythmia, high or low blood pressure, and rapid heartbeat.
- ◆ Gastrointestinal disorders: diarrhea, nausea and vomiting, stomach cramps, irritable bowel, rectal bleeding, and bloating.
- ◆ Muscles and joint problems: aches and pains, chills, shakes, burning, tightness, and numbness.
- ◆ Neurological disorders: depression, rage, anxiety, panic and mood swings; migraines; disorientation; dizziness; hyperactivity, behavioral problems, autism, and ADD in children; Alzheimer's; paralysis, numbness, tingling, sciatica and seizures; brain lesions.
- ◆ Respiratory disorders: asthma, chest pain and tightness, runny nose, and sneezing.
- ◆ Eye problems: blurry vision, difficulty focusing, augmentation of glaucoma, macular degeneration.
- ◆ Skin conditions: hives, rash, and flushing.
- ◆ Lethargy, sleepiness, and insomnia.
- ◆ Urinary tract and genital problems: frequent bladder pain, swelling of prostate or vagina, irregular menstrual spotting, and frequent urination.
- ◆ Extreme mouth dryness, mouth lesions, and swelling of face and tongue.

Where MSG is Always Present

Despite the harm caused by MSG, the FDA requires a "monosodium glutamate" label *only* for products whose ingredients are a 99% pure combination of glutamic acid and sodium. *Usually, foods that contain MSG do not have to be labeled as such.* Be aware that manufacturers are legally allowed to hide MSG under many different names. The following *always* contain MSG:

- ◆ Monosodium Glutamate (MSG), Monopotassium Glutamate (MPG).
- ◆ Glutamate, Glutamic Acid.
- ◆ Calcium Caseinate, Sodium Caseinate.
- ◆ Yeast, Yeast Extract, Yeast Nutrient, Yeast Food, Autolyzed Yeast.
- ◆ Corn Syrup Solids, Modified Corn Starch.
- ◆ Accent® and Aginomoto® (two brand names for the pure white crystals).
- ◆ AuxiGro®, a plant "growth enhancer" that is sprayed on growing crops (since approval from the US Environmental Protection Agency in 1998).
- ◆ Also present when the label says *disodium guanylate* or *disodium inosinate*. These food additives work synergistically with MSG, so are unlikely to be used if MSG is missing.

MSG is released from protein when the protein undergoes a process called *protein hydrolysis* (or simply *hydrolysis*), via either fermentation, chemicals or enzymes. The source of hydrolyzed protein could be anything. Although hydrolyzed proteins always contain MSG, the labels usually indicate a type of protein:

- ◆ Pea Protein (instead of simply "Pea")
- ◆ Corn Protein (instead of simply "Corn")
- ◆ Soy Protein (instead of simply "Soy")
- ◆ Wheat Protein (instead of simply "Wheat")

Note, pea protein powder is free of MSG if the *starch only* of the pea is treated—separated from the protein (customarily with enzymes and water), leaving the proteins intact. On the other hand, pea and other proteins always contain processed free glutamic acid if the *proteins themselves* have been at least partially hydrolyzed—split into their component amino acids.

The following products also *always* indicate the presence of MSG:

- ◆ Textured Protein, Textured Vegetable Protein (TVP), Vegetable Protein, Hydrolyzed Vegetable Protein, Hydrolyzed Plant Protein, Plant Protein Extract, Hydrolyzed Protein, Hydrolyzed Oat Flour—in short, *any protein that is hydrolyzed*.

Where MSG is Frequently Present

During processing, MSG can be created in certain food additives. So, the following *frequently* contain MSG:

- ◆ Carrageenan (either contains processed free glutamic acid or interacts with milk proteins in dairy products to produce MSG). Carrageenan is a thickening and binding agent that can cause inflammation, gastrointestinal disorders, and tumor growth.
- ◆ Maltodextrin, Barley Malt, Malt Extract, Malt Flavoring.
- ◆ Flavorings, so-called Natural Flavorings or Flavors (Chicken, Beef, Pork, etc.).
- ◆ Vegetable Broth, Hydrolyzed Vegetable Broth, Bouillon, Stock.
- ◆ Gelatin.
- ◆ Pectin.
- ◆ Seasoning, Spices (sometimes it's just spices, however—you need to ask the manufacturer).
- ◆ Soy Protein, Soy Protein Isolate / Concentrate.
- ◆ Soy Sauce (especially the cheap kind that hasn't been fermented properly for at least two years).
- ◆ Cheeses made with enzymes instead of rennet. Enzymes can create processed free glutamic acid because the proteins in the cheese are breaking down too rapidly.
- ◆ Whey Protein, Whey Protein Concentrate, Whey Protein Isolate. (Whey Protein from reputable companies should not contain MSG.)
- ◆ Protease Enzymes. (Protease supplements from reputable companies should not contain MSG.)

MSG could be in:

- ◆ Pre-packaged and frozen meals.
- ◆ Processed meats.
- ◆ Canned fish.
- ◆ Soups and stews.
- ◆ Chips, breads, crackers, and other snack foods.
- ◆ Gravy, bullion and stock.
- ◆ Salad dressing.
- ◆ Fast foods.
- ◆ Soaps, shampoos, hair conditioners, and cosmetics. (The MSG is hidden in ingredients that include the words "hydrolyzed" and "amino acids.")

- ◆ Dairy products: ice cream, frozen yogurt, low-fat milk. Many low-fat milks are made from powdered milk. Powdered milk includes free glutamic acid because of how it's processed. A dairy fortifies its milk with powdered milk to make the product legally acceptable. A product that's *ultra pasteurized* uses higher heat than normal pasteurization. This breaks down even more milk protein, causing such high levels of processed free glutamic acid that MSG-sensitive individuals experience adverse reactions.
- ◆ Binders and fillers for prescription medications, over-the-counter medicines and nutritional supplements; and fluids administered intravenously in hospitals. (According to the manufacturer, Varivax–Merck Varicella Virus Live vaccine contains L-monosodium glutamate and hydrolyzed gelatin, both of which contain processed free glutamic acid.)

MSG is Used Purposely

Manufacturers have known for five decades that MSG's effect on the brain makes it addicting. They purposely add MSG to food to make people buy and eat more of their products. The FDA claims that MSG is safe to eat in any amount—despite hundreds of scientific studies with titles like "The monosodium glutamate (MSG) obese rat as a model for the study of exercise in obesity"; "Obesity induced by neonatal monosodium glutamate treatment in spontaneously hypertensive rats: an animal model of multiple risk factors"; and "Hypothalamic lesion induced by injection of monosodium glutamate in suckling period and subsequent development of obesity."

MSG can cross the placenta and the blood brain barrier of a developing fetus during pregnancy, and portions of the blood brain barrier in adults. This is partly what makes it so dangerous. Another danger of MSG is that it upsets the amino acid balance in the body. The amino acid transport system is designed to convey small amounts of many amino acids at one time. But when abnormally large amounts of one or just a few amino acids flood the system, they displace other amino acids. We have more than enough glutamic acid in our diets. If there isn't enough dietary protein eaten to create "free glutamic acid," the body can create it from other amino acids.

The glutamic acid that's naturally present in intact, unprocessed proteins is beneficial—and nourishes us. The glutamic acid that's artificially created from a manufacturing process contains some of the same molecules that exist in antibiotics and in the cell walls of bacteria—and is carcinogenic. MSG is not a valuable nutrient or even a benign flavoring. It's a poison.

Fabricated Fats

Earlier in this chapter I discussed the need for Omega 3 fats in the diet. Preferred sources are grass fed beef and lamb, mercury-free fish, coconut oil, raw butter from grass fed cows, and perhaps fish or krill oil supplements.

Omega 9 fats, also beneficial, are in sunflower seeds, almonds, and olive oil. Omega 6 fats are in fresh, soaked nuts and seeds; but the Omega 6s that are in the many vegetable and seed oils on the market are mostly spoiled. The high heat used in the processing of almost every vegetable and seed oil turns those fats into rancid *trans* fats (short for “transformed” fats), whose rancidity is disguised with deodorizing and more processing.

Aside from the high heat and caustic chemicals, vegetable oils are ruined by a process called *hydrogenation*. The partial hydrogenation of plant oils, developed in the early 1900s, yields shortening and margarine—artificial products that are used worldwide. Hydrogenation involves the artificial manipulation of an oil’s molecular structure so that its inherent shape is changed. The substance becomes *saturated* with atoms of hydrogen gas; hence, the terms *saturated fats* and *hydrogenated fats*. Hydrogenation destroys any essential fatty acids that might have been present in the original oils.

The shape of a fat molecule indicates the compatibility (or incompatibility) of an oil product with living tissue. Molecules of healthy fats have a natural curved shape (giving them the name *cis*-fats), which helps build insulation on the cell membranes that protects the cells from chemical and bacterial invasion. Molecules of fake fats, on the other hand, are manipulated into being unnaturally straight. Your digestive system does not recognize these fake fats as food, and can’t break down or assimilate them. When the fake fat is incorporated into your own cellular structure, your cell membranes become stiffer—*partially hydrogenated, much like the material that was ingested*. Your now-malformed cell membranes also literally become perforated with holes, which allows chemical toxins, biological waste and other unwanted materials into the cells. Cellular metabolism becomes disturbed, unable to perform its usual processes. Simply put, the distortions in the molecules of fabricated fats cause your own body to become distorted, too, in both structure and function.

The goal of partial or total hydrogenation is to raise the burning temperature of the fats. This makes them more desirable for baking. It also extends their shelf life. Fake fats are unlikely to spoil, grow mold, or attract flies and rats. Because their excessive processing removes the nutrients, nothing can live on them, including you.

Fake fats create *free radicals*, atoms with too few electrons in the outer shell to maintain stability. The atoms

seek to add more electrons to their outer shell—either by combining with another atom (and thereby producing a more stable compound), or by knocking off an electron from another highly reactive atom. The atom that loses its electron in turn becomes a free radical, seeking to stabilize itself by finding an electron to steal from yet another atom. This starts a chain reaction of atoms that bombard the system like billiard balls. On a chemical level, this produces poisonous waste products.

One way to gain consumer acceptance of synthesized fats is to call them “healthy,” and state their origins in nuts or seeds. But even though an oil might be derived from even an organic seed, the end product is vastly different from the material of origin.

Most commercial baked goods and fast foods, which used to contain butter and lard, now contain *trans* fats. Even items from the health food store can be harmful. There are entire sections of dangerous oils, as well as foods made with such oils, falsely touted as healthy. Due to a loophole in the labeling laws of the United States, packaged foods marked “no *trans* fats” are actually allowed to contain a certain percentage of *trans* fats. This gives the false impression that the government is doing its job of protecting the consumer, while the labels are useless. If you want to avoid *trans* fats (not to mention GMOs and other fake foods and harmful ingredients), you should avoid packaged foods entirely.

It is not easy to get permission to tour an oil-pressing facility. Most oil companies do not like the processes to be too well known. . . . If more people knew about how oils are made, what they contain, and what has been taken out, more people would complain, and fewer would buy these oils. . . .

Fully processed oils are the equivalent of refined (white) sugars, and can therefore be called “white” oils. Like sugar, they are nutrient-deficient sources of calories, but in addition, they contain toxins that are not present in sugar [sucrose].

There is great resistance in the industry to make the changes necessary to produce natural, unrefined oils. . . . Changes would make large presses obsolete. Fresh edible oils require a higher level of care.

The care required to make fresh, unheated, EFA [essential fatty acid]-rich oils, with vitamins and minerals kept intact so our body can metabolize them properly, is not the present mandate of the mega oil industry; nor is a distribution system that gets fresh oils to consumers before they deteriorate from exposure to light and air high on their present list of priorities.

The Solution to Crime

Forget tougher punishments and hiring more police. The solution to crime and violence is on your dinner plate.

At first glance, there seems nothing special about the students at this high school in Appleton, Wisconsin. They appear calm, interact comfortably with one another, and are focused on their schoolwork. And yet a couple of years ago, there was a police officer patrolling the halls at this school for developmentally challenged students. Many of the students were troublemakers, there was a lot of fighting with teachers and some of the kids carried weapons. Today [a school counselor] describes the students as "calm and well-behaved." Fights and offensive behavior are extremely rare and the police officer is no longer needed. What happened?

A glance through the halls at Appleton Central Alternative provides the answer. The vending machines have been replaced by water coolers. The lunchroom took hamburgers and French fries off the menu, making room for fresh vegetables and fruits, whole-grain bread and a salad bar.

Is that all? Yes. . . . [The principal] is still surprised when she speaks of the "astonishing" changes at the school since she decided to drastically alter the offering of food and drinks eight years ago: "I don't have the vandalism. I don't have the litter. I don't have the need for high security."

It is tempting to dismiss what happened at Appleton Central Alternative as the wild fantasies of health-food and vitamin-supplement fanatics. And yet it is not such a radical idea that food can affect the way our brains work—and thus our behavior. The brain is an active machine: It only accounts for 2% of our body weight, but uses a whopping 20% of our energy. In order to generate that energy, we need a broad range of nutrients—vitamins, minerals and unsaturated fatty acids—that we get from nutritious meals. The question is: What are the consequences when we increasingly shovel junk food into our bodies? Do examples like the high school in Wisconsin point to a direct connection between nutrition and behavior? Is it simply coincidence that the increase in aggression, crime and social incivility in Western society has paralleled a spectacular change in our diet? Could there be a link between the two?

[A criminal-justice professor] has proven that reducing the sugar and fat intake in our daily diets leads to higher IQs and better grades in school. [After] a change in meals served at 803 schools in low-income neighborhoods in New York City, the number of students passing final exams rose from 11% below the national average to 5% above. [One study] showed that the number of violations of house rules fell by 37% when vending machines were removed and canned food in the cafeteria was replaced by fresh alternatives. [The professor] summarizes his findings this way: "Having a bad diet right now is a better predictor of future violence than past violent behavior."

In a prison for men between the ages of 18 and 21 in England's Buckinghamshire, 231 volunteers were divided into two groups: One was given nutrition supplements along with their meals that contained our approximate daily needs for vitamins, minerals and fatty acids; the other group got placebos. Neither the prisoners, nor the guards, nor the researchers at the prison knew who took fake supplements and who got the real thing. The prisoners given supplements for four consecutive months committed an average of 26% fewer violations compared to the preceding period. Those given placebos showed no marked change in behaviour. For serious breaches of conduct, particularly the use of violence, the number of violations decreased 37% for the men given nutrition supplements, while the placebo group showed no change. As a randomized, double-blind, placebo-controlled study, [the designer of the experiment, University of Oxford physiologist Bernard] Gesch emerges with convincing scientific proof that poor nutrition plays a role in triggering aggressive behavior.

After Gesch published his findings in 2002 in *The British Journal of Psychiatry*, the study was picked up by European and American media. The newspaper headlines were clear: "Healthy eating can cut crime"; "Eat right or become a criminal"; "Youth crime linked to consumption of junk food"; "Fighting crime one bite at a time." Then the media went deafeningly silent. Perhaps that's because . . . you can't get a patent on natural nutrients like vitamins and minerals. Far more effort goes into pharmaceutical, rather than dietary, solutions.

"Aggression is not only determined by nutrition," [Ap Zaalberg, working on nutrition with the Dutch Ministry of Justice,] states. "Background and drug use, for example, also play a role. Yet I increasingly see the introduction of vitamins and minerals as a very rational approach. . . ."

The British charity institution chaired by Gesch . . . estimates it would cost 3.5 million pounds (5.3 million euros or 6.4 million US dollars) to provide supplements to all the prisoners in Great Britain. That is only a fraction of the current prison budget of 2 billion pounds (3 billion euros or 3.6 billion US dollars). . . .

"Most criminal-justice systems assume that criminal behaviour is entirely a matter of free will," Gesch says. "But how exactly can you exercise free will without involving your brain? How exactly can the brain function without an adequate nutrient supply? Nutrition may actually be one of the most straightforward factors to change antisocial behaviour. And we know that it's not only highly effective, it's also cheap and humane. . . . We need to know more about the composition of the right nutrients. It could be the recipe for peace."

Food Conditioners

Food conditioner is a strange term. The need to “condition” food implies that the ingredient is not in an edible *condition* unless it’s radically altered. But in that case, is it really food? And if it’s not really food, should we be eating it?

One example of conditioning is the transformation of whole wheat into white bread. After the bran and germ are stripped from the wheat berry—leaving nothing but the starchy, non-nutritive white endosperm kernel—commercial flour mills use different chemical bleaches. The bleaches may include chlorine, benzoyl peroxide, potassium bromate, azodicarbonamide or nitrous oxide, mixed with various chemical salts to make the flour look even whiter (and presumably more attractive). The result is a substance called *alloxan*, produced when these chemicals combine with whatever proteins are still left in the flour.

Unlike the fairly benign bleaching agents used to whiten flour years ago, alloxan is a deadly poison. It’s even used to produce diabetes in research rats because it creates high levels of free radicals in the beta cells of the pancreas. Once the pancreas is damaged, it can’t secrete enough insulin, the body cannot properly metabolize carbohydrates, and glucose levels in the bloodstream rise, resulting in diabetes and Syndrome X. Alloxan is often used in conjunction with the artificial sweetener aspartame. Once aspartame damages the mitochondria (the fuel-burning units of the cells), it’s easier for the free radicals produced by the alloxan to cause even more DNA damage.

Thickeners and Emulsifiers

To provide a thick, creamy consistency to puddings, sauces and dairy products, the food industry routinely uses thickeners and emulsifiers, which *emulsify* or blend ingredients that don’t ordinarily mix well. Most of these additives are harmful.

Carrageenan, a gel, is commonly used in many foods. However, unlike Irish moss—a seaweed with thickening properties—carrageenan is a seaweed *extract*, refined with alkalis (caustic metal salts). This is why carrageenan triggers an inflammatory immune response. It can cause not only skin rashes, intestinal lesions and colitis, but also cancer. In fact, researchers deliberately use carrageenan to cause inflammation in animals when they test the anti-inflammatory properties of drugs. Another food thickener, maltodextrin, thins the protective barrier of mucus in the intestinal tract while simultaneously feeding a strain of *E. coli*. Two other emulsifiers, polysorbate 80 and carboxymethylcellulose (often found in items such as mayonnaise and ice cream), also erode the mucus.

Safe, natural (and more costly) thickeners include powdered tapioca, arrowroot, and kudzu root.

The Discoveries of Weston A. Price

To those knowledgeable about healthy food and native diets, Weston A. Price is a hero. He played a key role in helping to bring real food back into the diets of people not only in North America, but abroad. A prominent Canadian-born dentist (later resettled in the US), Price was the research head for the National Dental Association, with publication credits and a thriving practice. However, he was unhappy that dental problems were escalating and dentists weren’t able to help. So in the 1930s, he journeyed around the world with his wife for nearly a decade to learn what was so rapidly contributing to tooth decay in the modern “civilized” world. As 95% of American children today have dental deformities (which usually indicate other health problems as well), this journey was prescient.

Reasoning that the answer would be found if they studied healthy, rather than unhealthy, people, the Prices visited the Inuit (Eskimos) in Alaska; the Maori of New Zealand; the Australian Aborigines; the Malay tribes on islands north of Australia; Indians in north, west and central Canada; Indians in Florida and the western US; Melanesians and Polynesians of the South Sea Islands; isolated Gaelic folk living in the Islands of the Outer Hebrides off the coast of Scotland; Indians in the jungles of Peru; isolated Swiss in the Loetschental Valley enclosed by three high mountain ranges; and various African tribes living according to their ancient customs in what were then Kenya, Uganda, Rwanda, Belgian Congo and Ethiopia. Sometimes the Prices would have to spend weeks with the natives to gain their confidence and trust, before Weston could ask them questions about their health and diet through an interpreter.

Price’s fascinating book of his findings, *Nutrition and Physical Degeneration*, reads like a combination travelogue, anthropological treatise, restaurant review, and very readable text on medicine, dentistry and nutrition. The documentary photographs of dentally healthy and unhealthy people add great power to the text. “After spending several years approaching this problem [of what causes tooth decay] by both clinical and laboratory research methods,” he explained, “I interpreted the accumulating evidence as strongly indicating the absence of some essential factors from our modern program, rather than the presence of injurious factors. This immediately indicated the need for obtaining controls”—people who were not afflicted with the pathological condition he was studying. He continued:

To accomplish this it became necessary to locate immune groups which were found readily as isolated remnants of primitive racial stocks in different parts of the world. [Price used the word “primitive” not derogatorily, but to mean “original,

Vegetarianism and Pregnancy

Eating meat can elicit strong feelings, as evidenced by a heated, ongoing debate between people who don't eat animal flesh and those who do. The first group includes vegans, vegetarians, and lacto-ovo vegetarians (those who eat eggs and milk products, but not the animals that produce them). The second group ranges from those who eat only fish and/or poultry but no red meat, to total carnivores.

Weston Price's research is compelling because every healthy culture he visited included some meat in their diet. But a society's good health also depended on eating real food and not junk. Quite a number of modern vegetarians subsist on junk food, part of the Standard American Diet or SAD. (Many also eat purified wheat gluten. Popular as a meat substitute because it's chewy, it wreaks havoc on the body.)

Studies show that pregnant women who eat an unbalanced diet high in sugars and empty carbohydrates—typical of many vegetarian diets—give birth to children with birth defects, lowered immunity, and structural abnormalities. But even if a vegan mother doesn't eat junk, she will still have trouble achieving a nutritionally balanced diet. Vitamins A and D (which help us absorb the minerals in food), Vitamin B6, and the minerals calcium, magnesium, iron, zinc and copper, are much more easily absorbed from animal foods than plant foods. Nutritionists have found that the majority of vegetarians and vegans suffer from a shortage of Vitamin B12, which is found only in meat and other animal products. And we now know that many cases of Alzheimer's—whose early signs include fatigue, tingling in the hands and feet, sleep disorders, and a tendency toward irrational anger—may actually be a Vitamin B12 deficiency. Compared to modern diets, traditional diets contain four times the amount of calcium and other minerals, and ten times the amount of fat-soluble vitamins A, D, E and K.

My own observations parallel Price's research. I know a vegetarian man and woman who never wanted to hear about the dangers of soy, let alone the benefits of eating meat. The woman's first pregnancy ended in a miscarriage and her first living child suffered from severe allergies. In children born to SAD parents, I see consistently poor teeth: crooked, with spaces in between. Or they're lodged high in the gums, growing at irregular angles—definitely not like the pearly whites of Price's beautiful natives.

Nevertheless, some people insist how much better they feel when avoiding meat. They also believe that their vegetarian or vegan children are healthy. Only time will tell. But in the meantime, is it fair to the health of a future child to be so rigid about diet?

simple, basic," to signify connection to one's roots.] A critical examination of these groups revealed a high immunity to many of our serious afflictions [afflictions] so long as they were sufficiently isolated from our modern civilization and living in accordance with the nutritional programs which were directed by the accumulated wisdom of the group. In every instance where individuals of the same racial stocks who had lost this isolation and who had adopted the foods and food habits of our modern civilization were examined, there was an early loss of the high immunity characteristics of the isolated group. These studies have included a chemical analysis of foods of the isolated groups and also of the displacing foods of our modern civilization.¹²⁹

Price's illustrated book is over 500 pages, condensed from his meticulous field notes and his huge collection of photographs of people with good and bad teeth. The book discusses not only dietary habits, but also lifestyle, social customs, attitudes, and birthing practices. The natives who still followed their traditional diets, based on locally-grown foods in season, enjoyed excellent general physical health as well as healthy, well-formed teeth.

"Traditional" diet depended on what was native to the region. The Inuit's diet consisted of about 80% fat, along with the meat they hunted. The Scottish people of the Outer Hebrides lived on plenty of seafood with oat cakes (oats were one of the few crops that could grow on that perpetually cloudy, damp island). The South Sea Islanders enjoyed coconut and a wide variety of other tropical fruits, along with roasted wild pig and crab. And the Swiss ate lots of cheese and butter with their sourdough bread. Interestingly, fewer than 10% of the traditional cultures Dr. Price studied consumed dairy on a regular basis.

Natives always ate the organs, glands, and fat of an animal along with the muscle meat. Eggs of all kinds were also eaten. Significantly, the milk, cheese and butter from the animals they raised were eaten either raw or (more often) fermented. Some of the natives ate great quantities of meat; others ate much less. But every culture—even those who subsisted primarily on vegetables or on large amounts of grains and legumes—ate some form of animal protein, even if it consisted of insects (10%, in one case). In fact, certain worms high in fat were considered a great delicacy in certain parts of Africa. (In modern Zimbabwe, these worms are still popular at markets because they are the only protein that many people can afford.) Price, who apparently preferred not having to eat animals, was disappointed that during his travels he did not discover even one vegan group.

In every case, the onset of degenerative disease was caused by the introduction of processed adulterated food—largely white flour and white sugar—from white civilization, which became available to the natives when new roads were built or more foreign ships visited an island. Significantly, the children of women who deviated from their traditional diets all had narrow dental arches and misaligned teeth, and were much more susceptible to diseases such as tuberculosis and arthritis. If the women resumed their native diets, the babies they subsequently bore were healthy. The children of well-fed parents didn't cry much (if at all), and they were remarkably independent. Those on traditional diets were content and even-tempered, even in oppressive climates.

Dr. Price found great wisdom in how the natives prepared their food. It either was eaten raw, was minimally cooked, was subjected to extended cooking (often after being soaked), or was fermented raw. All of these methods made the food much more assimilable.

Today, we know that raw fruits and vegetables contain enzymes and especially high concentrations of vitamins and minerals. Raw or low-heat dehydrated meats also contain enzymes. Parasites sometimes present in raw meat are less inclined to grow in a healthy body; but Price found that antiparasitic condiments were often eaten with the raw meats to help prevent or decrease harmful effects. For example, wasabi (a root comparable to horseradish) is a traditional Japanese staple with sushi or raw fish. The soaking of seeds and nuts, and in some cases the removal of the skins, neutralizes their enzyme inhibitors. The soaking of grains and beans (usually overnight), and subsequent slow cooking, help break down the indigestible fibers and complex sugars. Soaking and sprouting (and fermenting, about which Price did not make extensive comments) also neutralize the anti-nutrients. One anti-nutrient is the phytic acid (the plant's natural preservative) in the outer layer which, if not transformed, combines with minerals in the intestinal tract and blocks their absorption.

One of Price's most important discoveries was the presence of a fat-soluble activator in fish eggs, shellfish, lard, cod liver oil, and milk and organ meats from grass fed animals. This activator, which we now know to be Vitamin K2, plays an essential role in the body's absorption and utilization of many minerals, and helps prevent dental caries (cavities) and insulin resistance.

It's not surprising that native populations all over the world were much healthier before the introduction of commercialized, refined Western non-foods. The rule for healthy eating is simple: "Whole foods." The farther away food is from its origin, the less nutrition it provides. At some point on the processing continuum, food becomes either non-food or even anti-food. Anti-food—comparable

to cigarette smoke and drugs, which the body was never designed to ingest—burdens the system with synthetic substances that lack life energy (electromagnetic charge), and forces the body to deplete its nutrient stores as it attempts to eliminate the poisons.

My favorite cookbook—*Nourishing Traditions: The Cookbook that Challenges Politically Correct Nutrition and the Diet Dictocrats*, by Sally Fallon and Mary Enig—is founded on the discoveries of Weston Price and other nutritionist giants. Like Weston Price's own work, this is a multi-dimensional book, full of outstanding recipes as well as interesting and essential scientific information that explains why these recipes are included. Many types of food preparation that help optimal assimilation are explained in detail, including slow cooking, fermentation, soaking, and sprouting. Cooking meat and bones for at least six hours diffuses, into the water, the calcium and other nutrients from the marrow, gelatin, bones and connective tissue—thus providing a mineral-rich, nutritious broth. Fermentation, from the infusion of beneficial bacteria, makes food more assimilable due to the pre-digestion process that begins outside the body. Dairy is best eaten either raw or fermented. Small amounts of fermented vegetables (such as cabbage), eaten with each meal, add valuable enzymes and friendly flora that aid digestion. Soaking grains removes some of the indigestible compounds, and sprouting adds life force.

Nourishing Traditions is indispensable for those interested in learning how to prepare foods in ways that have sustained human populations for millennia.

Animals are smarter than humans when it comes to feeding their children

Humans are the only species on the planet who actually go out of their way to feed their children crap. All other animals instinctively seek out the best nutrition they can find. . . . But humans? Most of them "reward" their children with junk food, sugary sodas, candy laced with petrochemical coloring additives and refined sugars that promote obesity and diabetes. Most parents don't even make any real effort to follow nutritional discipline at home—they simply buy whatever their children saw advertised on television, caving in to the all-powerful "nag factor" that junk food companies fully exploit when marketing to children.

As a result, *human children are the least healthy youngsters of any species on the planet.* Baby dolphins are healthier than baby humans, for example, and they are born with healthier nervous systems, fewer toxins and a lot more common sense.

Food Preparation and Preservation

Basics of Cooking

Cooking is actually quite simple. It changes the structure of food via hot water, hot fat, dry hot air, or moist hot air. When foods are heated, the molecules move faster and heat up too, and there's a corresponding chemical change in the proteins, fats, and carbohydrates in the food.

With air heating, food is placed in an open space (barbecue pit, uncovered pot) or enclosed space (clay oven, pit covered with rocks or leaves, covered pot). With water heating, water either completely surrounds the food (boiling), covers the bottom of the pan (poaching), or covers the bottom of the pan while the food rests on mesh away from the water (steaming). With fat heating, a small amount of oil is used (sautéing), a larger amount is used (frying), or oil completely covers the food (deep frying).

This is not a cookbook, so I will focus on approaches that either negatively impact health or strongly favor it: two methods of cooking (frying and microwaving); some food preservation techniques; the special category of raw food preparation; and finally, cookware.

Frying

Most oils degrade when heated. The only edible fats and oils that can be heated to a degree, without suffering molecular damage or nutrient loss, are virgin olive oil, butter (or its clarified form, ghee), and coconut oil. Virgin olive oil can withstand only moderate heat; butter a bit more; ghee even more; and coconut oil, fairly high temperatures for both frying and baking. You can tell that the oil is overheating when it starts to smoke. It makes no sense to use unheated oils in an effort to avoid trans fats, but then ruin them with super high heat to fry food.

Frying, and especially deep frying, damage food by creating toxic compounds. These compounds impair cell respiration and inhibit immune function, thus encouraging disease conditions. Oils chemist Udo Erasmus bluntly states: "Oil kept at 215°C (419°F) for 15 minutes or more consistently produces atherosclerosis when fed to experimental animals."¹³⁰ The damage comes from:

rapid oxidation and other chemical changes that take place when oils are subjected to high temperature in the presence of light and oxygen. First, antioxidants in the oil (Vitamin E and carotene) are used up. Then . . . free radicals [are produced] that start chain reactions in oil molecules. Under these conditions, many chemical changes take place in oils.¹³¹

The oxidation that takes place in fried (heated) oils causes some of the oil molecules to become fragmented,

and some molecules to join that had not been joined previously.

More than oils suffer during frying. *Foods* fried in these oils also undergo destructive molecular changes that toxify the body. *Acrylamides*, created when oils heat food at very high temperatures, make fried foods delicious and crisp. They also cause cancer and nerve damage.

How likely is the chance of being toxified by acrylamides? One Canadian author writes:

Both the Food and Drug Administration (FDA) in the US and Health Canada [similar to the FDA] have evidence that carbohydrate based products heated to 350°F [about 177°C] or more produce . . . acrylamides. . . . A bag of potato chips can have 500 times the amount of acrylamides allowed in drinking water. A single chip may contain as much acrylamides as allowed by Health Canada in an 8-ounce glass of drinking water.¹³²

As Erasmus points out, foods that have turned brown are burned, their nutrients destroyed. "Proteins turn into carcinogenic acrolein. Starches and sugars are browned (caramelized) through molecular destruction. Fats and oils are turned to smoke by destruction of fatty acids and glycerol."¹³³ Frying's not a great option, especially for the very sick, but Erasmus does offer an alternative that helps protect the essential fatty acids (and our health). It requires more care, but is worth the effort.

Traditional Chinese cooks first put water in their wok, not oil (North American Chinese cooks have largely abandoned this wise practice). Water keeps the temperature down to 100°C (212°F), a non-destructive temperature. In European gourmet cooking, vegetables [are] placed in the frying pan *before* oil is added to protect oil from overheating and oxidation. The food tastes less burned, retains more of its natural flavors and nutrients and, most important, supports our health better.¹³⁴

Heavily fried foods can be tasty; so if you eat them, balance the meal with antioxidant foods, such as raw juices, salads, green smoothies, and perhaps berries. Also take extra Vitamin C and drink plenty of water.

Meats that are barbecued or charbroiled cause problems similar to frying. Those tasty charcoaled carcinogenic substances are called *heterocyclic amines*, or HCAs. If you like barbecued meats, marinate them first in apple cider vinegar and one or more of the following herbs. Or simply rub a few onto the meat: oregano, thyme, rosemary, basil, cumin, garlic. These healthful additions will hinder the formation of HCAs—and taste great.

Microwaving

Microwaving has become a popular method of cooking food, especially for those who love gadgets and fast food. To cook food, microwave ovens emit a 2.45 gigahertz (2,450,000,000 Hz) signal. While such food is convenient and fast, the price we pay is high. We can distinguish between the effects of microwave radiation on the water in the food (and thus on the food itself); on the body, once the food is ingested; and on the body by just the ovens, independent of the ingestion of food. I will discuss each in turn.

The ability of microwaves to cook food is based on its effects on water, which exists in all plants and animals (and our food) and is very sensitive to radiation. You may recall from earlier in this chapter that one end of a water molecule has a positive charge and the other end has a negative charge. When subjected to microwave radiation, the water molecules in the food reverse in polarity: the positive ends become negative and the negative ends become positive. This back and forth movement happens continually, and at high speeds—up to one hundred billion times a second! The molecules are jostled so much that the repeated motion creates friction, which emits the heat that cooks the food. The disruption of the water molecules is so intense that they are literally torn apart and become structurally deformed. Chemists even have a name for this phenomenon: *structural isomerism*.

What happens to microwave oven-cooked food as a result of this rapid, chaotic polarity switching? The food becomes radically altered. “In most research [conducted by the Russians],” William Kopp writes, “the foods were exposed to microwave propagation at an energy potential of 100 kilowatts per cubic centimeter per second, to the point considered acceptable for sanitary, normal ingestion.”¹³⁵ Under these “acceptable” conditions, the naturally occurring chemical bonds between various elements in the food are shattered, causing the molecules to fragment. Chemists have a name for this phenomenon as well: *radiolysis*, the molecular disintegration resulting from radiation. This causes the formation of new *radiolytic compounds*, involved in the following:

- ◆ Naturally occurring amino acids (which comprise protein) in milk and grains transform into carcinogenic poisons that damage the nervous system and kidneys.
- ◆ Microwaved meats contain d-Nitrosodienthanolamines, a class of well-known carcinogens.
- ◆ Even brief exposures of raw, cooked or frozen vegetables to microwaves enhance the production of toxic alkaloids, many of which become carcinogenic. (Belladonna, morphine, and strychnine are alkaloids.)

- ◆ There’s a 60% to 90% decrease in the availability of nutrients, including Vitamins A, C, E and B-complex, essential minerals, choline, inositol, and methionine.

Microwaves transform more than our food—they influence all body systems. Once you understand how microwaves affect water, you can grasp how living cells are affected by the microwaved foods. A practitioner writes:

The cells are actually broken, thereby neutralizing the electrical potentials, the very life of the cells, between the outer and inner side of the cell membranes. Impaired cells become easy prey for viruses, fungi and other microorganisms. The natural repair mechanisms are suppressed and cells are forced to adapt to a state of energy emergency; they switch from aerobic to anaerobic respiration [in other words, the behavior of cancer cells]. Instead of water and carbon dioxide, the cell poisons, hydrogen peroxide and carbon monoxide, are produced.¹³⁶

Here is a partial list of the damage that people can suffer from eating microwaved foods:

- ◆ Abnormal increase in leukocytes, white blood cells whose elevated numbers usually signify pathogenic effects such as poisoning and cell damage.
- ◆ Nervous system damage: electrical functioning is impeded and messages cannot be transmitted properly.
- ◆ Cardiovascular disorders, including the blockage of coronary arteries and an increase of heart attacks.
- ◆ A disruption in the electrical potential of the cellular membranes, which impedes the efficiency of nutrients that enter the cells and wastes that leave.
- ◆ A higher-than-normal percentage of cancerous cells in the stomach and intestines, resulting in digestive disorders, impaired excretory function, and a statistically significant increase in stomach cancer.
- ◆ Decrease in levels of hemoglobin, the iron-containing pigment in red blood cells that binds to oxygen and carries the oxygen from the lungs to all the tissues.
- ◆ Decrease in levels of lymphocytes (white blood cells).
- ◆ Hormonal imbalances.
- ◆ Significant loss of vital energy.
- ◆ Significant levels of disruption in alpha, delta, and theta brain waves, resulting in psychological disorders including memory loss, inability to concentrate, diminished intellectual function, and interrupted sleep.

Microwaved foods contain “hot spots” that can make food explode and cause burns when you touch it. The toxic chemicals in packaging can leach into the food. Most important, the radiation emitted by even a *correctly working* microwave oven disrupts the electrical fields of those nearby (microwaves travel easily through inside walls). Newer research, published in a 2010 *European Journal of Oncology* monograph by Dr. Magda Havas and colleagues,¹³⁷ shows that radiation of 2.4 GHz from a cordless phone base—the same frequency used by wireless routers and baby monitors as well as microwave ovens—disrupts the heart and autonomic nervous system. The levels tested were *below* federal safety guidelines. Other research in the same publication shows that virtually every function of the body is disrupted: amino acid formation, brain cognition, cell differentiation and enzymatic activity, collagen synthesis, and immune response.

Microwaving can have immediate fatal consequences too. In 1991, a woman named Norma Levitt entered an Oklahoma hospital for hip surgery and received a blood transfusion. A nurse warmed the blood for the transfusion in a microwave oven, and in an hour and a half Levitt was dead. We may reasonably conclude that

it wasn't the surgery or anesthesia that killed her, but the deformed, lifeless blood cells in the transfused blood.

The story of how microwave ovens came to be accepted, even eagerly embraced by the American public, is similar to how harmful drugs have reached the marketplace: via suppression of negative evidence. As reported in “Microwave Tragedy,” in 1991, Dr. Hans Ulrich Hertel of the Swiss Federal Institute of Technology, and Dr. Bernard H. Blanc of the University Institute for Biochemistry, published the results of a thorough clinical examination of microwaved nutrients and their effects on the blood and human physiology. Among their findings was an alarming increase of leukocytes (white blood cells), which indicates abnormal conditions such as poisoning or cell membrane damage—and which can lead to cancer. At the time, Hertel was employed by a major international food company. It fired him “for questioning certain processing procedures *that denatured the food.*” [emphasis added]¹³⁸ In 1992, the Swiss Association of Dealers for Electro-apparatuses for Households and Industry pressured a Swiss court to issue a gag order against the doctors. In March 1993, Dr. Hertel was prohibited:

from declaring that food prepared in the microwave oven shall be dangerous to health and lead to changes in the blood of consumers, giving reference to pathologic troubles as also indicative for the beginning of a cancerous process. The defendant shall be prohibited from repeating such a statement in publications and in public talks by punishment laid down in the law.¹³⁹

The legal decision was finally reversed in 1998 by the European Court of Human Rights. It ruled that Hertel's rights had been violated and Switzerland must pay him compensation. However, by then millions were indoctrinated. Today, many Americans naively believe that microwave ovens are safe.

Not all countries allow microwave cooking. Research on the biological effects of microwaves was conducted as early as 1942 at Humboldt University in Berlin, Germany. The Russians—who since 1957 extensively studied the effects of microwave ovens at the Institute of Radio Technology—initially made their use illegal, and issued a warning about the biological and environmental damage resulting from appliances that use this frequency. (Unfortunately, the ban was later lifted.) Other Eastern European countries also set limits for microwave oven usage.

Simply put, because microwaved food is chemically and molecularly altered, its nutrients are lost and harmful compounds are created. The body, exposed to foreign and dangerous substances and further deprived of the

Pottenger's Cats

Between 1932 and 1942, physician Francis Pottenger Jr. conducted a study on 900 cats to see the effects of a diet consisting of raw vs. cooked food. In his book, *Pottenger's Cats: A Study in Nutrition*, he described the diet. All cats received cod liver oil. Some cats were fed both raw milk and raw meat. Others ate pasturized and/or processed (condensed) milk and cooked meat. Still others were given a combination of cooked and raw in the same meal—either raw meat and pasteurized/processed milk, or cooked meat and raw milk.

Only the cats on a completely raw diet thrived. Through multiple generations, they had excellent health and strong immune function, were of normal size, had friendly temperaments, and reproduced easily. Cats fed even a partially cooked diet experienced miserable health. Those that didn't die after a year had offspring that could not reproduce beyond the third generation.

Even the cat excrement, when tested as fertilizer, mirrored the health of the cats themselves. Plants would not grow when given waste from cats that had eaten any cooked food at all.

Pottenger won many awards in his lifetime, was appointed to numerous prestigious posts, and published over fifty articles on nutrition and chronic disease. No one has yet tried to duplicate his research.

nutrients it needs, becomes sick. No wonder cancer rates are especially high in people who eat microwaved food!

Not all technology is bad. As Hertel himself once said, “We, the scientists, carry the main responsibility for the present unacceptable conditions. It is therefore our job to correct the situation and bring the remedy to the world. I am striving to bring [humankind] and techniques back into harmony with nature. We can have wonderful technologies without violating nature.”¹⁴⁰

(Incidentally, the sun emits microwave radiation. However, unlike the excessively high-powered, *alternating* current from microwave ovens (which changes the polarity of the water molecule), the sun’s microwave radiation is low-powered, pulsed, *direct* current that does *not* create heat through friction. See Chapter 1 and Appendix C for details.)

Even the best organic food is ruined by microwaving. If you eat in a restaurant, make sure that your food is not being prepared or heated in a microwave oven.

Freezing

In general, frozen foods have very good nutritional value. Commercially frozen foods are cooled as soon as they’re picked (produce) or killed (fish and meats). Frozen foods should not contain preservatives or ingredients to preserve color, as these chemicals are unnecessary and toxic.

Fermenting

No one knows how fermentation began. The best guess is that some of the most common foods we enjoy today evolved serendipitously. An often-told story involves milk. Carried across the desert in animal skins, the milk absorbed the bacteria in the skins and curdled, resulting in yogurt and cheese. Every country in the world has its own fermented specialties. Kvass originated in Russia. Umeboshi plum paste, kim chee and miso were produced in Asia. Sauerkraut was popular in Germany. The range of fermented foods is practically unlimited because meats, milk, vegetables, fruits, and grains can be fermented.

The fermentation process always involves bacteria, and sometimes yeasts. It is the *enzymes* from these infinitesimal microorganisms that break down substances, both inside and outside the body. In his excellent book on how to make fermented foods, Sandor Katz writes that not all bacteria are our enemies.

Microbial cultures are essential to life’s processes. . . . We humans are in a symbiotic relationship with these single-cell life-forms. . . . [They] digest food into nutrients our bodies can absorb, protect us from potentially dangerous organisms, and teach our immune systems how to function. . . . They keep the soil fertile and comprise an

indispensable part of the cycle of life. . . . Certain microorganisms can manifest extraordinary culinary transformations. . . . The process of fermentation makes food more digestible and nutritious. Live, unpasteurized, fermented foods also carry beneficial bacteria directly into our digestive systems, where they exist symbiotically, breaking down food and aiding digestion.¹⁴¹

Vinegar, a popular fermented food, can be beneficial or damaging depending on how it’s made. Naturally brewed vinegar is created by fermenting grains or fruits to produce alcohol, and then letting the liquid sit in the presence of oxygen until it’s transformed into vinegar. White distilled vinegar contains acetic acid. Wine vinegar contains mostly acetic acid, and sometimes tartaric acid as well. The acetic acid in white distilled and wine vinegars destroys red blood cells and interferes with digestion, impeding the assimilation of food. Acetic acid also contributes to cirrhosis (hardening) of the liver, and duodenal and intestinal ulcers.

Raw, unpasteurized apple cider vinegar contains malic acid. The malic acid in apple cider vinegar helps provide energy to muscles, assists in the coagulation of blood, and contributes to healthy blood vessels. Apple cider vinegar is high in potassium, which is used by the body for nerve and muscle function, the regulation of blood pressure, and blood sugar level balance. It seems clear that vinegar made with anything other than *raw* apple cider is a poison. Vinegar should never be heated. If you don’t have a source of apple cider vinegar, get some unpasteurized (unheated) apple cider and allow it to sit for several weeks.

Despite the benefits of fermented foods, people with *Candida* infections may have a cross-sensitivity to many types of yeasts and fungus, and thus become more ill when they eat fermented foods. As usual, pay attention to how your body responds.

Canning

According to an FDA estimate, 17% of the US diet comes from commercially canned food. Although canned goods are convenient, most of them (except for meats) are not very nutritious. Also, unless the cans are lined with safe enamel—which very few manufacturers use—their coating makes the food outright dangerous.

Two chemicals, bisphenol-A (BPA) and bisphenol-S (BPS), are used to line metal cans. Both disrupt the body in ways that are similar to the effects of synthetic (*pseudo*, or false) estrogen. Pseudo-estrogens from plastic are similar enough to the real hormone that they attach to the body’s estrogen receptor sites, displacing the body’s own naturally produced estrogen. But they are also foreign enough to cause great damage. They impair hormone

function, causing early puberty, lowered sperm counts, and infertility. They damage the nervous system and brain, impairing learning and causing hyperactivity. They increase the formation of fat, causing obesity. And they impair immune function and cause cancer. Damage to cells can occur at concentrations as low as 2 ppb (parts per billion). According to the Centers for Disease Control, levels of 2 ppb were found in 95% of the people examined.

A study overseen by the Environmental Working Group found BPA in over 50% of all name-brand canned goods tested. This includes canned infant formula. Many of the cans contained BPA levels 200 times higher than the government's safe level for industrial chemicals. One to three servings of some canned foods (including chicken soup, ravioli and infant formula) are sufficient to cause harm. Bisphenol compounds are also widely used to make some types of hard plastic bottles, which should be avoided as well.

Home canning, using glass jars, is safe and practical (if time-consuming).

Drying

Long ago, our ancestors discovered that drying meats, vegetables and fruits in the sun was a convenient way to both preserve food and carry it on journeys. Today, tropical items like coffee beans and cacao are dried in the sun, but especially in technologically advanced countries, foods are dried in electric dehydrators. Although dried foods are portable and lightweight, their low water content may make them too rich and concentrated. Therefore, some people prefer to soak dried foods in water before eating them, or at least drink plenty of water while eating.

Raw

Once you start investigating healthy ways to eat, you'll eventually find advocates of eating all foods uncooked—completely raw. Raw food proponents say that their food is alive, and there's some sound science that supports this. First, the enzymes in raw foods are intact. *Enzymes*, the chemical catalysts of all life processes, are naturally present in all living organisms: humans, animals, plants. When foods are eaten raw, the enzymes they contain help our bodies digest them.

Biochemists have long known that excessive heat destroys enzymes. Opinions vary about what cooking temperatures deactivate the enzymes in food, but the average estimate is 110°F (43.3°C) or higher. This is a huge issue for raw foodists, because many of them dry their foods to concentrate the flavor. Further complicating the temperature estimate is the varied water content of foods: they dry at different rates, which means that they require different temperatures and different drying times. The ideal drying temperature is also unreliable because the

amount of heat cited for optimal drying is usually that of the air, which at the start of the drying process is usually much higher than the temperature of the food. We know only that nutrients and enzymes are preserved in foods that are dried slowly, and at low enough temperatures.

Enzyme-wise, not all foods are created equal. The most abundant sources of food enzymes are raw meats, fish and dairy; raw honey; pineapple and unripe papaya (which contain bromelain and papain, respectively); other fruits including grapes, figs, avocados, dates, bananas, kiwi and mangos; extra virgin olive oil; sprouted grains, beans and legumes; wine and unpasteurized beer; and fermented dairy products. Fruits and vegetables that are pickled or fermented when raw generally have more enzymes too.

Enzymes are only part of the reason that raw foods are alive. Raw foods also contain negative hydrogen (H⁻) ions instead of positive hydrogen (H⁺) ions (as discussed in the **Water** section of this chapter). Albert Szent-Gyorgyi, the famous Nobel laureate who discovered Vitamin C, showed that an electron cannot move in a living system unless it's accompanied by hydrogen. The H⁻ ions in raw foods, which fundamentally indicate vitality, are completely absent from cooked food. H⁺ ions acidify the system and speed the aging process, while H⁻ ions alkalize the system and delay aging. Negative hydrogen ions also support metabolic functions, facilitate the elimination of wastes, and escort absorbable minerals into the tissues. This explains why people feel heavier in their digestive tracts when they eat cooked rather than raw foods.

Scientist Patrick Flanagan, who studied the work of Szent-Gyorgyi, understood that the "fountains of youth" throughout history are based in truth. The long-lived Hunzas, who dwell in an isolated valley in Pakistan, drink glacial water that's not only rich in minerals, but also contains an unusual form of spherical silica. This silica imparts H⁻ instead of H⁺ ions to the water. After finding high H⁻ ion levels in the healing waters of Lourdes in France, in Baden-Baden in Germany, and in Pagosa Springs in Colorado (US), Flanagan invented a silica supplement that duplicates the action of these waters. Negative hydrogen, he wrote, "is the carrier of all electrons in all chemical reactions. . . . Our bodies desperately need it."¹⁴²

The third, very important reason that raw foods are alive is their biophoton content. *Biophotons* are the smallest known units of light. With wavelengths measuring between 380 and 780 nanometers, their luminescence is much too low to be seen by the naked eye. But their existence was proven in 1974 by the scientist Fritz-Albert Popp. Biophotons are stored in and emitted by living things: the sun, humans, animals, plants. All cellular DNA uses biophotons to communicate information that controls complex bodily processes and confers energy and vitality.

How to Feed Your Dog or Cat

If you think that you're doing your beloved animal companion a favor by buying only the "best" commercial chow—dried pellets called *kibble*—this may change your mind. Most kibble contains some or all of the following: hormones, antibiotics, artificial dyes and preservatives, sugar, and harmful chemicals such as MSG. The FDA allows pet food to contain up to 15% of its total weight in corn syrup. "Vegetable protein" on a label can legally consist not only of corn and soybean meal, but also rice husks, peanut shells, and other waste materials from the milling of grain. Even if the kibble contains *whole* grains, this is not a natural part of a pet's diet. High-cellulose "vegetable protein" can only be assimilated by cows, sheep, and other grazing animals whose digestive tracts are designed to break it down (and even then, they should be eating grass rather than grain). If the label reads "animal byproducts," "meat or bone meal," or "meat digest," your dog or cat might be ingesting fur, hair, feathers, leather, nails, or hooves. Although technically these can be considered the food's "protein content"—and the labeling is legal—this waste offers no nutrition. Your pet cannot digest or assimilate it.

In most states, it's legal for the diseased parts of chickens, cows and other slaughterhouse animals that failed inspection for human consumption to become food for pets after being "cleaned" with toxic petrochemical solvents. The Food and Drug Administration, California Veterinary Medical Association, American Veterinary Medical Association and other groups, admit that when animals in shelters and pounds are euthanized, their carcasses are often sent to pet "food" processing plants. Some of the euthanized pets contain sodium pentobarbital (a drug used to kill them), which does not get broken down in processing. Also, the animals might be wearing their flea collars when added to the mix. If this sounds too unbelievable, don't take my word for it. In the last two decades, exposés of pet food have appeared in newspapers, holistic magazines, veterinary journals, and even the pet food industry's own magazines.

Even presumably wholesome products, which boast the absence of artificial preservatives and glutinous grain, contain some sticky carbohydrate—such as potato or corn starch—to bind the materials together. These carbs are not natural to a dog's or cat's diet.

The dietary guidelines in this chapter that you use for yourself can be adapted for your domesticated animal friends. Advocates of a healthy diet for dogs (and cats)—following the advice of Australian veterinarian Ian Billinghurst, who discovered that his dogs' health problems disappeared when he fed them natural, raw food meals similar to those of their ancestors—call it the BARF diet. BARF is an acronym

for "Bio Active Raw Food" or, more popularly, "Bones And Raw Food." The BARF diet recognizes that animals in the wild—lions, tigers and cheetahs (relatives of the house cat), and wolves, jackals and coyotes (relatives of the dog)—are carnivorous. Members of the dog and cat families eat their prey raw—plenty of muscle, organ meats, and bones—after they kill it; and they don't cook their food before eating.

Like their cousins in the wild, domesticated dogs and cats need lots of protein. They thrive on raw meat, with raw egg and occasionally raw milk (especially for cats). Tripe—the first three stomachs of ruminants, along with the partly digested, fermented plant material—provides valuable probiotics. It smells awful to humans, but most dogs love it. In lieu of tripe, some owners feed ground up (and sometimes fermented) vegetables with the raw meat. Raw bones containing marrow, cartilage and gristle should be given to dogs at least once a week, along with enough meat to cushion the hard bone. Unlike unsafe cooked bones, raw ones don't splinter, they help clean the animals' teeth, and they satisfy the natural instinct to gnaw.

Cats are noted for requiring high amounts of the amino acid taurine. While other mammals are able to synthesize taurine from other amino acids in the body, cats cannot; so taurine must be supplied by their diet. Never feed your pets sugar—or chocolate, which contains theobromine that can kill them in high enough amounts.

A raw diet requires ample stomach levels of hydrochloric acid, which kills bacteria in raw meat. Animals heavily damaged by poor diet and vaccines often fare better initially with cooked food. They can thrive on raw if you add a little bit at a time to their usual food, eventually making their entire meal raw. (Enzymes and probiotics supplements help digestion.) Sick animals may require homemade cooked food for brief periods.

Ironically, until very recently "pet" food did not exist. Dogs ate table scraps and raw bones, and were much healthier than they are today. Our pets are the innocent victims of an improperly regulated, billion-dollar-a-year industry's unscrupulous business practices. Think how you would feel if you ate the same devitalized, canned or dried dinner every single day—let alone material that was contaminated with other diseased animals, foreign chemicals and miscellaneous indigestible substances. Wouldn't you be sick, too? No wonder so many dogs and cats suffer from flatulence, allergies, itchy skin, dull fur, vomiting, heart disease, dental problems, kidney and liver failure, and cancer!

If you take the time to love your pets in this way, you will save lots of money on veterinarian bills—and your animal friends will be healthier and happier.

We know that DNA vibrates several billion times a second, expanding and contracting like a coil. Studies have shown that each time a contraction occurs, one single biophoton (light particle) is produced, conveying information to other biophotons in the same body, and to biophotons in other bodies. All of the biophotons that are emitted surround the body in a highly structured field.

“The more light a food is able to store,” writes osteopath Joseph Mercola, “the more nutritious it is. Naturally grown fresh vegetables, for example, and sun-ripened fruits, are rich in light energy. The capacity to store biophotons is a measure of the quality of your food.”¹⁴³ Most raw foodists say they feel not only much lighter physically as a result of eating raw, but also more spiritually connected. This is undoubtedly a direct result of the light quotient that their bodies are receiving.

Flexible raw foodists may eat fermented dairy and pastured eggs, but the most vocal proponents of a raw diet tend to be strict vegans. The diet focuses on uncooked and fermented fruits and vegetables, and soaked or sprouted grains, nuts and seeds. However, the metabolic needs and relatively sedentary lifestyle of many people make it difficult for them to handle high-carbohydrate nuts and grains without adding at least some animal protein to their diets. A lesser known raw foods protocol is the so-called Paleolithic or Primal diet. Beef is either eaten raw, or slowly dehydrated into jerky at minimal heat to preserve the enzymes. Fish is “cured” with lemon juice and salt—the equivalent of slow cooking without heat, which does not destroy the enzymes. Perhaps people would want to eat more raw foods if they were encouraged to substitute meat and fish (even if cooked) for some of the recommended grains, nuts and seeds. As for the dangerous parasites in some raw meats, freezing is an acceptable alternative to heating. Freezing beef—and even fish and pork, especially susceptible to parasites—for three weeks, and then marinating these meats in an acidic medium such as raw apple cider vinegar or citrus juice, kills the parasites.

There are many reasons for eating a raw (and vegan) diet. For some, this type of eating makes the difference between remaining ill and becoming well. However, a raw vegan diet is not for everyone. As Annemarie Colbin points out, most people who live in cold climates need the heat that cooked food provides. And those who perform heavy manual labor, work with computers, or spend lots of time under fluorescent lights, need the slow steady energy from cooked foods as opposed to the quick, but short-lived, bursts of high energy generated by raw foods.

Cooking does have its place. Many foods are relatively unusable unless they are altered in some way. For instance, even with rigorous chewing, humans cannot digest the

tough cellulose of many vegetables, such as kale, potatoes and carrots. That is why many vegetables require at least a minimal amount of steaming. Cooking allows the vitamins and other nutrients in many vegetables to be assimilated. It’s worth losing enzymes and some nutrients through cooking if it makes the difference between eating a vegetable and not eating it at all. Vegetables can always be juiced to obtain the valuable nutrients.

The potent energy in raw foods is probably the most useful for recovering the strength and vitality that are lost due to illness. “Mono” diets are chiefly designed to manage extreme health issues. Once a condition is eliminated, continuing what was originally a corrective diet may create another imbalance or even illness. You don’t have to adhere to a 100% raw diet in order to benefit from these vital, living foods. Consider eating at least some living foods every day as part of your overall nutritional program. One of my favorite raw diet books, with tasty recipes and lots of thought-provoking information, is *Hooked on Raw*, by Rhio.

Cookware

With all this focus on food, it’s easy to forget about the pots we use. But cookware can make a huge difference to our health.

Aluminum used to be one of the most common materials used for cookware. But it’s a toxic metal, poisonous to the body in any form. Tomatoes, lemons, vinegar, and other acidic foods will leach aluminum from a pot. High levels of aluminum are found in the brains of people with Alzheimer’s and other diseases. Keep in mind that the use of aluminum foil can produce the same effects.

Aluminum pots and pans are less common now, but so-called non-stick Teflon® cookware has become popular. This coating, created by the DuPont company, contains PFOA, short for *perfluorooctanoic acid*. According to a statement by the United States Environmental Protection Agency,

PFOA . . . [sometimes called “C8,” is] a synthetic . . . chemical that does not occur naturally in the environment. Companies use PFOA to make fluoropolymers, substances with special properties that have thousands of important manufacturing and industrial applications. Consumer products made with fluoropolymers include non-stick cookware.¹⁴⁴

Another fluoropolymer is PTFE, short for *polytetrafluoroethylene* (also spelled *polytetrafluorethylene*). In discussions about Teflon®, the acronyms “PTFE” and “PFOA” are sometimes used interchangeably.

Fluoropolymer resins were developed in 1938 by scientists working for DuPont, environmental consultant Roberta C. Barbalace reports:

This new polymer seemed almost indestructible and its qualities promised to make it profitable if they could just find the right market. It was patented in 1944 and used first to line equipment used in the enrichment process of U-235 uranium hexafluoride gas for the Manhattan Project [the building of atomic bombs by the United States] during WW II. DuPont reserved its entire output for government use for the duration of the war with about two-thirds of it being used for the Manhattan Project.

When the war was over, DuPont had to find a new use for its polymer. In 1953, Teflon® was marketed to commercial users. . . . Before long . . . most of the industrialized world was cooking with Teflon®-lined pans. Teflon® products have been made from a variety of polymers.¹⁴⁵

DuPont's polymers were used in semiconductors, wire insulation and gaskets; and as coatings for clothes, carpeting, furniture and non-stick cookware—because, as the manufacturer states, they resist high temperatures, chemical reactions, corrosion, and cracking due to stress.

Non-stick coating on cookware is a really good idea. The problem is, the coating begins to break down and emit fumes when it's exposed to even moderate heat. Reviews of health records of workers exposed to the chemical, as well as animal studies, show numerous health risks associated with PFOA. Among them are:

- ◆ Chills and headache.
- ◆ Fever between 100° and 104°F (about 37.8° to 40°C).
- ◆ Prostate toxicity, tumors and cancer.
- ◆ Toxicity and impairment of the brain, kidneys, liver and thymus.
- ◆ Respiratory problems, including difficulty breathing, tightness of chest, coughing, sore throat, fluid in the lungs, and death by suffocation.
- ◆ Changes in size of the pituitary gland (which controls metabolism, growth and reproduction) *at any amounts*.
- ◆ Birth defects and death.

The dangers of Teflon® became well publicized when a 1995 article by Joanie Doss appeared in *The Alaska Club Bird Newsletter* and was then circulated on the Internet. Doss, a professional bird trainer, began researching the

compound after her beloved parrots died in her kitchen while she was cooking in non-stick pots. Compared to humans, birds are tiny and have extra-sensitive respiratory tracts; so they react much sooner to toxic air. “In 1951,” Doss wrote, “the first case of human suffering from tetrafluoroethylene problems was reported. It produces flu like symptoms in humans. The tetrafluoroethylene lingers long after the product has been removed.”¹⁴⁶

At what temperature does Teflon® break down? DuPont's own website states that the coating withstands up to about 500°F or 260°C (so why are consumers advised to use only low or moderate heat?), and that the coating starts decomposing only if temperatures reach above 600°F (316°C)—at which point, it can emit fumes that cause a flu-like condition (but it's temporary!).

The Environmental Working Group commissioned its own studies and reached very different conclusions.

A generic non-stick frying pan preheated on a conventional, electric stovetop burner reached 736°F [391°C] in three minutes and 20 seconds, with temperatures still rising when the tests were terminated. A Teflon® pan reached 721°F [383°C] in just five minutes under the same test conditions, as measured by a commercially available infrared thermometer. DuPont studies show that the Teflon® offgases toxic particulates at 446°F [230°C]. At 680°F [360°C] Teflon® pans release at least six toxic gases, including two carcinogens, two global pollutants, and MFA [monofluoroacetic acid], a chemical lethal to humans at low doses. At temperatures that DuPont scientists claim are reached on stovetop drip pans (1,000°F) [537.8°C], non-stick coatings break down to a chemical warfare agent known as PFIB [perfluoroisobutene], and a chemical analog of the WW II nerve gas phosgene.¹⁴⁷

Telling cooks to use Teflon® cookware according to ridiculously strict and impractical guidelines indicates a failure to take responsibility for making unsafe pans. Not many cooks will apply a thermometer to the bottom of their pans to measure the temperature. Even if the pans are used within the recommended temperature limits, as soon as the cookware becomes scratched its coating peels and disperses into food. Teflon® is the most widely known brand of non-stick cookware, but there are many others including Duracote™, Excalibur®, Fluron®, Greblon®, Silverstone®, Supra®, T-Fal®, Resistal®, and Xylon®.

An Internet search conducted in March 2008, using the words “DuPont,” “lawsuit,” and “Teflon®” together, yielded almost 20,000 findings. Here are some highlights:

- ◆ In 2005, DuPont agreed to pay up to \$343 million in a settlement of a class action lawsuit instituted on behalf of nearly 70,000 people living near a DuPont plant in Parkersburg, West Virginia. DuPont had polluted the water in the Ohio River south of their plant with PFOA, resulting in birth defects, cancers, and other ailments. DuPont agreed to clean the water and pay to monitor the health of affected residents. Not surprisingly, the company is now trying to renege on its legal obligations.
- ◆ In March 2006, a panel of EPA scientists recommended that the agency formally label PFOA a likely carcinogen.
- ◆ In April 2006, DuPont settled a lawsuit from the EPA, which claimed that DuPont had been hiding health data about PFOA for decades. DuPont was fined \$10.25 million.
- ◆ In May 2006, twenty states and the District of Columbia filed multiple class action lawsuits against DuPont. Hundreds of internal documents showed that the company knew about the health risks of Teflon® since 1961, but failed to disclose them.

Reviewing court documents, Barbalace commented:

By 1984 DuPont was aware of . . . major problems with the production of Teflon®: Chemicals associated with the production of Teflon® had been linked to medical problems with workers, including polymer fume fever, leukemia, and liver damage. They had been linked to medical problems with test animals, including leukemia, cancer and reproductive dysfunction. Chemicals associated with the production of Teflon® had been linked to birth defects in humans and test animals. Chemicals associated with the production of Teflon® had been shown to accumulate in the blood of exposed individuals. Teflon® had been shown to offgas free radicals that can form toxic fumes at temperatures much lower than reported by DuPont.¹⁴⁸

Manufacturers stopped making PFOA in 2015. However, other products have taken its place that are chemically similar, made with perfluorocarbon (PFC) and perfluoroalkyl substances (PFAS). Scientists worldwide are correctly pointing out that *all* of these fluorine-based substances are carcinogenic. (Besides cookware, these chemicals are used as stain- and water-repellants for

clothing, carpets, furniture, bedding, food containers, and even some brands of dental floss.)

Safe materials for cookware have existed for awhile. These include heat-resistant glass, ceramic (enamel) over cast iron, plain cast iron, and stainless steel. Corning Vision® glassware is strong and easy to clean. High quality enamelware won't easily chip; but if it has a red, orange or yellow glaze, it may contain cadmium, so buy other colors. Plain cast iron lasts a lifetime if you dry it immediately after washing it and regularly *season* it, which means coating it with food oil to prevent rust. Cast iron is a great choice if you don't mind the weight of the pot or any iron that may leach into food, which occurs if you use something acidic like tomatoes, lemon or vinegar. Surgical quality stainless steel heats well, is easy to clean, and reportedly the metal doesn't leach into food due to its dense molecules.

Demands from health-conscious consumers and celebrity chefs have inspired manufacturers to seek new ways of producing non-toxic cookware that works well. In the past several years, a few companies have emerged to fulfill the

marketplace demand for non-stick cookware that's safe. One brand is Starfrit, which makes the chemical-free "Rock" line using high-impact metal pellets that harden the surface metal into a non-stick finish. There will undoubtedly be even better pots from other companies as the technology becomes perfected.

It's worth spending a little extra money to ensure that your cookware is safe.

Enjoy What You Eat

Diets are as varied as people. Someone whose immune function is compromised will require a food plan that's different from what a healthy person needs. And a person will require different nutrition at different times. However, everyone needs clean, drinkable water and wholesome, properly prepared food.

If you're feeling reasonably stress-free, have generally been well nourished, *and* are in good health (this last point is very important!), eating foods that are not on your meal plan once in a while won't hurt you. It can also be a lot of fun. I have seen people become as ill from the rigidity of their attitudes as from the junk they ingest. However, whether you're well or ill or somewhere in between, try to avoid foods that are genetically modified. GM foods raise toxic pesticide loads and quickly destroy the beneficial gut flora. Should you "fall off the diet wagon," enjoy what you're eating, forgive yourself, and eat better the next day.

LEGAL INGESTIBLES WITH PHARMACOLOGICAL EFFECTS

Sometimes, people who are otherwise careful about their diet ingest food, beverages or inhalants whose negative effects earn them the nickname “recreational drugs.” The pharmacological effects of caffeine, alcohol, and tobacco are well known and their legal status is currently stable. The pharmacological effects of cannabis depends on the forms in which it’s used. Its legal status is arbitrary, depending on the whims of lawmakers.

Chocolate

Chocolate is cherished worldwide, including in the US. Some sources estimate that it comprises a full one percent of the average American’s diet. But even though many consider chocolate a food, it has so many pharmacological effects that it’s really a drug. This, along with recent extensive publicity rhapsodizing the health benefits of chocolate, makes it worth exploring whether chocolate is worth eating, how much, and under what circumstances.

Chocolate is derived from the seed or “bean” of the cacao fruit, which grows on a tropical evergreen tree belonging to the species *Theobroma cacao*. The cacao tree grows along the equator, mainly in South America and Africa. Its foot-long pods contain up to 50 seeds, each about the size of a lima bean, that are surrounded by a sweet, pulpy fruit. Long before the cacao bean was used for the chocolate confections of today, the fruit was used to make a fermented, mildly alcoholic beverage.

The Mayans were the first to use cacao, but it was the Aztecs who popularized grinding the seeds into a powder that was made into a beverage. To the ground beans, the Aztecs added hot water and spices (often chile pepper), but never sugar. This cacao beverage was not a dessert—it was drunk only by the nobility, priests, revered warriors and merchants, and honored guests. The Aztecs believed that cacao imparted strength, stamina and wisdom, undoubtedly due to the chemicals in the bean. Cacao contains over 300 chemical compounds, but it’s the stimulants that exert the strongest and most discernable effects. I’ll discuss the major stimulants first: caffeine, theobromine, theophylline, and phenylethylamine.

The caffeine content of a 1.4-ounce (40 gram) piece of chocolate is sometimes compared to the amount in one cup of decaffeinated coffee. But the “decaffeination” of coffee is a misnomer, as all coffee labeled “decaf” contains *some* caffeine; and the standard for decaf coffee ranges from as little as 5 mg to a whopping 258 mg per cup. (The average amount in a cup of decaf averages around 30 mg, depending on the origin of the coffee.)

One cup of cocoa contains only about 5 mg of caffeine. But even a small amount of caffeine can trigger a stress response. As discussed earlier in **Popular Beverages and “Health” Drinks**, caffeine abounds in coffee, cola drinks, and chocolate. Most people agree that there’s nothing redeeming about soda pop. But opinions vary greatly about coffee, and especially chocolate. Among other effects, caffeine irritates the gut (causing diarrhea, and sometimes nausea and vomiting). It damages the nervous system (causing mental hyperactivity and then fatigue). And it stresses the heart (causing rapid, irregular heartbeat). Caffeine also depletes serotonin, an important neurotransmitter already deficient in many people.

It’s true that one may feel more alert and energetic when eating chocolate (or drinking coffee). But this is due to an outpouring of adrenal stress hormones (including epinephrine); and eventually, with continued use of the caffeinated product, the adrenals become depleted. Epinephrine increases blood sugar levels, insulin resistance, and fat storage.

The alkaloid compound theobromine, another powerful stimulant, is abundant in cacao. It affects the cardiovascular, nervous, and urinary systems. In very small amounts, theobromine can induce mental and physical relaxation. But if ingested in larger amounts, theobromine can cause rapid and irregular heartbeat, nausea, migraines, increased urination, and sweating. People may respond negatively to even a very small amount of chocolate because of the theobromine, which incidentally is highly toxic to dogs in any amount (because they metabolize cacao so slowly). Like caffeine, theobromine can also cause insomnia, tremors, anxiety, and mental confusion. When the body metabolizes caffeine, even more theobromine is produced. This compound is so powerful, it has been used medicinally: to dilate blood vessels, as a diuretic, to stimulate the heart, and to promote weight loss.

Theophylline is another stimulant in cacao, although in only trace amounts. It’s used by modern medicine as a drug to treat asthma and other respiratory conditions. Warnings for its “side” effects mention symptoms similar to those of theobromine and caffeine, especially in those who are already sensitive to it.

Of all the stimulants in cacao, the most famous besides caffeine is probably phenylethylamine, abbreviated PEA. PEA is nicknamed the “love molecule” because it’s produced naturally in the brain in small amounts when someone is in love. This is why women especially turn to chocolate when a love affair has ended: chocolate’s PEA content simulates the effects of being loved, thus helping to postpone the inevitable grief over the loss of a lover. Molecularly similar to amphetamine and the

neurotransmitter dopamine, PEA stimulates dopamine receptors, thus increasing the speed at which information flows between nerve cells. In small amounts, PEA acts as a mood elevator, creating endorphins that induce euphoria and sometimes insatiable desire. PEA also helps increase energy and enhance alertness. But when ingested in chocolate—which contains higher and more potent levels than those normally found in the brain—PEA’s effects are very similar to those of amphetamine: decreased appetite, augmented heart rate and blood pressure, increased breathing rate, raised blood sugar levels, and sometimes even paranoia.

Other chemicals in cacao include tannic acid (tannins), which exist in greater amounts than they do in tea. Tannins bind to proteins and other nutrients, and prevent them from being utilized by the body. The phytic acid in cacao also binds minerals. It inhibits the activity of some digestive enzymes and promotes gut inflammation, leaky gut, and autoimmune disorders. Oxalic acid, present in cacao in high amounts, inhibits calcium absorption. Cacao beans may also contain aflatoxins, which can develop during fermentation (discussed shortly).

So far, I have focused on the mostly negative effects of the strong stimulants and some other chemicals in cacao beans. What about the beneficial components that have recently been touted by both the lay and medical communities? The beans do contain flavonoids (which protect delicate blood vessels), and antioxidant polyphenols (which fight free radicals in the body). (Two of these antioxidants are resveratrol, which is also in red wine, and catechins, which are also present in green tea.) Cacao contains anandamide, a messenger molecule that attaches to the cells’ receptor sites for pain relief, and which influences appetite, depression, fertility, memory, and higher thought processes. “Anandamide” is derived from the word *ananda*, which means “extreme delight” or “bliss” in Sanskrit. Not surprisingly, the molecular structure of anandamide is very similar to that of tetrahydrocannabinol—the ingredient in marijuana that causes the “high.” Cacao is also noted for being very high in magnesium, a mineral that is responsible for countless body functions and is usually deficient in the majority of the population. People with chocolate cravings often need the magnesium that it contains.

Another vital substance in cacao beans is tryptophan, an essential amino acid that the body cannot manufacture itself and must obtain from food. Tryptophan is the only substance that can be used to create serotonin, a vital neurotransmitter. Serotonin is involved in bone

metabolism, appetite and temperature regulation, learning, memory, sleep, wound healing, and in the proper function of muscles, the endocrine system and cardiovascular system. However, this neurotransmitter is probably best known for stabilizing mood and increasing feelings of well-being—a state that has created many chocoholics.

Chocolate companies make a point of citing cacao’s content of bioflavonoids, antioxidants, anandamide, magnesium, and tryptophan. But what about the harmful stimulants? And is raw cacao different from roasted? Some claim that raw is better than roasted because it

possesses the benefits without the drawbacks. To answer these questions, let’s take a quick look at how chocolate is produced.

In the manufacture of any cocoa product, the cacao pods are broken open and the seeds are removed from the fleshy fruit pulp. Then the beans are fermented in heaps under loose cloth

or plastic covers, which allow air to pass through for several days. As any remaining fruit liquifies and drains away from the solids, the chemical composition of the beans changes. They lose some of their bitterness and astringency, and acquire more robust, complex flavors. Then the beans are dried (“cured”) for another week, either in the sun or with electrical drying equipment. Next, pieces of pods and other debris are removed from the dried beans. Each cacao bean is actually a series of tiny long pieces or nibs, covered by a thin husk of dried fruit skin that’s like flimsy tissue paper. These husks must now be removed—either by hand, by machine, or with streams of air (presumably warm). At some point during fermentation, the bean’s naturally occurring fat, called “cocoa butter,” is separated (extruded) from the bean. It will be added back to chocolate bars, but not powder.

Further processing depends on whether commercial cocoa or raw cacao is being made. For raw, the beans are “cold pressed”—ground between very heavy granite millstones or stainless steel plates, presumably at minimal heat. Ideally, the temperature for cold pressing remains at 104°F (40°C), but the friction always produces some heat, and temperatures can reach a high 120°F (49°C)—enough to kill the beneficial living enzymes. Manufacturers of conventionally processed cocoa aren’t concerned about maintaining minimal heat, but to dedicated raw foodists, the heat issue is critical. Also, during fermentation, the temperature of the bean mass can sometimes rise to 118°F (47.8°C) or higher; so without personally monitoring the factory, there’s no way to know if a cacao producer’s claims are true. Also, no independent verification exists for “raw.”

Strength is the capacity to break a chocolate bar into four pieces with your bare hands—and then eat just one of the pieces.

—Judith Viorst
*Love and Guilt and the
Meaning of Life, etc., 1987*

The most important, major difference between raw cacao and conventional chocolate is that the heavily processed product is always roasted. This may be done either before or after the beans are crushed into pieces or further ground into powder. Roasting gives the cacao a more intense, presumably more desirable “chocolate” taste—or at least what we have been taught to associate with chocolate. Roasting temperatures most often range from 221°F (105°C) to 248°F (120°C), which means that all of the enzymes and a fair portion of other beneficial nutrients are destroyed.

The final difference between raw cacao and processed cocoa is that almost all conventionally manufactured chocolate is subjected to “Dutching,” or “Dutch processsing,” so named because a Dutchman invented the method. Raw cacao has a naturally acidic pH of between 5 and 6, which makes it extremely bitter. During Dutch processing, the cocoa is washed with a caustic potassium carbonate solution (later removed), which neutralizes its acidity, conferring a neutral pH of 7.0. This makes the processed cocoa more mellow, although it’s still quite bitter. Dutch cocoa is a very dark brown, while raw cacao is much lighter in color.

Dutching (alkalizing) the cacao degrades it, apart from the damage caused by roasting it at high heat. A 2008 study, published in the *Journal of Agricultural and Food Chemistry*, compared the antioxidant efficiency in cocoa that had been Dutched lightly (with a pH of 6.5–7.2), moderately (with a pH of 7.21–7.6), and heavily (with a pH of 7.61 and higher). Untreated cacao had the highest count of polyphenols and flavanols. The lightly Dutched chocolate only retained about 40% of the flavanols, and levels in the heavily Dutched chocolate were reduced to only a little over 10%.¹⁴⁹

In general, dark chocolate is reported to contain about twice as many antioxidants than red wine, and almost three times more antioxidant power than green tea. (Dark chocolate is always recommended because the dairy in milk chocolate prevents the body from absorbing the antioxidant polyphenols.) But these statistics can be deceptive. Chocolate studies don’t mention if the cacao being tested was raw, roasted, or roasted and Dutched. Most people don’t eat their chocolate raw—so how realistic are the studies? And dark chocolate contains some sugar to make it less bitter—so how healthy is it?

Compared to roasted beans, raw cacao is indeed higher in beneficial nutrients. It’s true that because bioflavonoids help the body metabolize nitric oxide (a gas that helps relax blood vessels), the flavanols in cacao may likewise protect the heart and lower blood pressure. And it’s true that flavanols (such as those in cacao) are

powerful enough to deactivate the free radicals present in cancerous tissue. The problem is, the cacao flavanols don’t exist independently of the stimulants, which are called “stimulants” for a reason: they work like drugs, overstimulating or mimicking the neurotransmitter receptors in the brain, in the same ways that cocaine, morphine and opiates do. In genuinely raw cacao, the nutrients are protected. But so are the stimulants! Despite glowing reports on chocolate, evidence strongly suggests that benefits of its nutrients are overshadowed by the toxic effects of the stimulants—for all but the healthiest. People with adrenal or chronic fatigue, autoimmune disorders, *Candida albicans* overgrowth, cardiovascular problems, chemical sensitivities, diabetes, digestive issues, fibromyalgia, food addictions, food intolerances, hormonal imbalances, and neurological disorders (mood swings, anxiety, migraines, neurotransmitter imbalances), are unlikely to benefit from roasted or raw cacao. I admit that raw cacao does feel lighter and more “alive” to me, and I feel less jittery from raw than from processed dark chocolate. Nevertheless, I still feel better if I indulge in tiny amounts, and only rarely.

Considering the damage caused by the stimulants in cacao, health claims for it—better insulin acceptance, protection of the nervous system, reduced risk of cardiovascular disease and stroke, lowered blood pressure, inhibition of brain inflammation that causes migraines, and even reduced risk of certain cancers and slowing of the aging process—appear outlandish.

There are other ways to obtain the beneficial nutrients of chocolate. The amino acid tryptophan, which increases serotonin levels in the body, is in free range turkey, wild fish, grass fed beef, whey, pastured eggs, and nuts. A small amount of carbohydrate eaten with the protein helps clear all of the amino acids except tryptophan from the bloodstream, which allows tryptophan to cross the blood brain barrier, unimpeded, to form serotonin. Some of the best complex carbohydrate foods for this purpose include bananas, sour cherries, and buckwheat. Foods high in magnesium include dark leafy greens, pumpkin seeds, and avocado. Bioflavonoids are abundant in peppers, broccoli, and citrus fruits. And plenty of fresh produce contains antioxidants. Before you decide to devote more of your food budget to chocolate, you might want to weigh the advantages against the disadvantages.

One more thing. Often, cacao is picked by young children under 12 years of age who are being forced to work under slave conditions. Some companies, aware of this exploitative practice, are making efforts to hire only adults and to pay them a living wage. This is known as *fair trade* chocolate, and the labels will indicate this.

Alcohol

An alcoholic beverage is technically the waste product of certain types of yeasts that feed on fruit and grain sugars. Wines and brandies are fruit-based, and beer and “hard” liquors such as vodka (that have a higher alcohol content) are grain-based. What the yeast is fed, and the kind of yeast used to create the drink, determines the beverage.

Alcohol impairs immune response. A diuretic, it forces the kidneys to excrete water that’s needed by the tissues. And it’s an anti-nutrient, affecting the body in ways similar to sugar (another refined carbohydrate). The body expends valuable vitamins and minerals to metabolize alcohol and detoxify from it. Women metabolize alcohol differently from men and are more susceptible to its negative effects, but it damages the following in everyone:

- ◆ *Cardiovascular system.* The heart muscle may become abnormally stretched, resulting in irregular heartbeat, high blood pressure, blood clots, and heart attacks.
- ◆ *Liver.* Due to its excessive toxic load, the liver is unable to detoxify from both the alcohol and its toxic byproducts (including ammonia), setting the stage for the development of fibrous growths, excessive fat (known as “fatty liver”), and inflammation (including cirrhosis, in which the biliary ducts are blocked).
- ◆ *Pancreas.* Alcohol causes blood sugar problems due to its easy absorption into the bloodstream and inflammation of the pancreas. Its breakdown waste product, *acetaldehyde*, can cause nausea and vomiting, abdominal pain, diarrhea, fever, and sweating.
- ◆ *Brain and nervous system.* Alcohol damages the branch-like ends of the nerve cells, which slows and scrambles nerve impulses and impairs neurotransmitter production. This results in sleep disturbances, anxiety, depression, mood and personality changes, motor coordination problems, the inability to focus, and even coma and death.

Intoxication from alcohol equals the destruction and death of brain cells. *It’s the death of brain cells, which leads to impaired transmission of electrical impulses, that provides the alcoholic high.* Note the word “toxic” in *intoxicated*. Alcohol poisons the liver and clogs the lymph vessels with waste. A hangover is literally lymph poisoning.

Don’t be fooled by claims that red wine confers health benefits. Wine is made from grape pulp and also its *skin*, which is the part of a red grape that’s rich in beneficial antioxidants. You can eat plain grapes for the antioxidants. If you want to drink, find an organic beverage without sulfur or sulfite preservatives. It will taste better, too.

Tobacco

Tobacco is part of this discussion because it’s a legal drug that’s widely used, sometimes in lieu of food. As incredible as it sounds, in the 1950s and 1960s doctors (or actors portraying doctors) appeared on television, in movie trailers, and in magazine and newspaper ads, alleging that smoking cigarettes was good for you. The ads claimed that more doctors smoked Lucky Strikes (or whatever brand was being endorsed) than any other brand. Or, there was “not one single case of throat irritation due to smoking Camels.”¹⁵⁰ Mickey Mantle and other sports heroes were paid to recruit new smokers. Today these ads seem quaint and amusing, but we now know that cigarettes are harmful and can kill. We also know that for decades, cigarette companies were well aware of the dangers of smoking but did not disclose these dangers, at the expense of people’s health and lives.

The harm of tobacco—whether smoked as cigarettes, inhaled (“vaped”) as e-cigarette vapor, or inhaled/chewed as snuff powder—is thoroughly documented. In addition to lung cancer, asthma, bronchitis, coronary disease, emphysema, pneumonia, strokes and tuberculosis, more recent studies prove that smoking is a causative factor in kidney disease, diabetes, infections, intestinal disorders, and more heart and lung ailments not previously linked to smoking. Nicotine causes *neutrophils* (a type of white blood cell) to release inflammatory molecules called *neutrophil extracellular traps* (NETs), which depress immune function. E-cigarettes and snuff increase the incidence of cavities, gum disease, mouth ulcers, and mouth cancer. Moreover, the metallic coils of many e-cigarettes release significantly toxic levels of lead, nickel, arsenic, and other heavy metals.

Smoking is linked to more than twelve types of cancer alone, largely due to the chemicals—sweeteners, preservatives, fire retardants and other toxins—added to the tobacco to make the cigarettes taste appealing (and be more addictive). All the major tobacco companies do this. When burned, these additives form over 4,000 even more poisonous chemical compounds. Just a few of these poisons—which are known carcinogens—include carbon monoxide (a deadly gas); acetaldehyde (a waste product in gasoline and excreted by the *Candida albicans* fungus); formaldehyde (used to embalm corpses); cyanide and arsenic (recognized poisons); lead (a deadly heavy metal that’s against the law to put in paints because it causes brain damage in children); chloroform (used as anesthesia); benzene (an industrial solvent); ammonia compounds (which increase the speed at which nicotine reaches the brain); and levulinic acid (which desensitizes the upper respiratory tract, thus reducing the harshness of the nicotine and augmenting the smoker’s tendency to

The Biochemistry Behind “Recreational” Drug Use

Some people inherit a special body chemistry, called sugar sensitivity, which sets them up to develop specific behavioral and psychological traits. Sugar-sensitive people generally have a family history of alcoholism and are very fond of sweet foods and carbohydrates. They are likely to be impulsive in general, may be compulsive about eating or other behaviors, and may be overweight and/or depressed. They may gain weight disproportional to the amount of calories they consume. They feel both physical and emotional pain more deeply. They may have unexplained or disproportionate anger, overreact to stress and fail to get the results they hope for in psychotherapy. Many have experienced childhood trauma or abuse. . . .

Low levels of serotonin are associated with obesity, carbohydrate craving, depression, impulsivity and violence. Low serotonin levels are also involved in depression . . . [and] can cause overwhelming sugar cravings. Many people with bulimia have insufficient supplies of serotonin. Lack of serotonin can disrupt your sleep patterns and lead to insomnia. Migraine headaches are the result of low serotonin levels. Lowered levels of serotonin are also associated with alcoholism. People who have experienced Post Traumatic Stress [Disorder] (PTSD) show decreased levels of serotonin as well.

Serotonin levels are increased during the intake of addictive substances, such as alcohol, tobacco, certain narcotics and caffeine. When individuals attempt to kick these habits, they often develop a chemical withdrawal syndrome when serotonin levels plummet. During withdrawal, patients get the “munchies” . . . overeating [that] in part, is related to chemical dependency withdrawal, a response to low serotonin levels. These same low serotonin levels may also be partly related to the severe depression and sleep deprivation that occur during withdrawal. Low serotonin levels make the withdrawing addict more prone to use addictive substances as the body tries to compensate for its serotonin loss.

Because serotonin directly regulates the body’s response to pain, and affects other neurotransmitters involved in pain control (like endorphins), maintaining adequate serotonin levels can relieve such painful syndromes as fibromyalgia, chronic fatigue syndrome, and premenstrual syndrome. Low levels of endorphins may make you feel depressed, impulsive and victimized. You may be touchy and tearful. And you will have a desperate craving for sugar.

Narcotics such as morphine, heroin and codeine, work like endorphins because their molecules have the same shape. They can fit into the endorphin receptor sites and fool the brain into thinking that natural endorphin was sent. Alcohol, through not acting on the receptors directly (like narcotics), . . . causes the brain to release additional endorphins to produce the [alcoholic drinking] “high” . . .

This heightened vulnerability to the effects of alcohol, opiate drugs and sugars may be particularly true for certain groups, including alcoholics and heroin addicts, women and obese men, and persons from families at risk for alcoholism—all known to have low levels of endorphins. Consequently, the experience of emotional stress by these groups may well lead to increased use of opioid-medicating substances. And use of moderate amounts of sugars or alcohol may well prime greater use of these relief-producing substances and lead to compulsive, long-term addiction.

5-hydroxytryptophan (5-HTP) is a substance that occurs naturally in the human body and helps in the manufacture of serotonin, a brain chemical that is associated with the feeling of well-being and fulfillment. 5-HTP [also] increases beta-endorphin levels, as well as levels of other brain chemicals, including dopamine and noradrenaline. The ability of 5-HTP to affect brain chemicals in the indoleamine family, as well as their cousins the catecholamines, helps explain why it has such a broad spectrum of effects throughout the body. 5-HTP can be particularly important for the sugar-sensitive personality. Laboratory tests show that people who have chronic complaints such as stress, depression, chronic fatigue syndrome, and fibromyalgia have low levels of endorphins. In Europe, 5-HTP has been used for decades as an approved treatment for depression, sleep problems, weight loss, and other medical complaints. [Editor’s note: *many people do better with plain tryptophan.*]

Three natural herbals can complement and enhance the benefits of 5-HTP (besides providing benefits of their own) for the sugar-sensitive person. The first is the relatively unknown Indian herb, *Gymnema sylvestre*—called the “anti-sugar” herb for its ability to cut back/stop sugar cravings—which has been used by Indian healers for nearly 2,000 years and has long been associated with alternative medicine. Another important herb for the sugar-sensitive person is *Ginkgo biloba*. This herb is an effective antidepressant, in part because it counteracts one of the major changes in brain chemistry associated with aging—the gradual reduction in the number of serotonin receptor sites. Besides increasing the number of serotonin receptors, *Ginkgo biloba* may also enhance the effects of 5-HTP by inhibiting the MAO enzyme. [And] *Ginkgo biloba* extract is effective in the treatment of decreased blood flow to the brain.

To enhance the effects of 5-HTP for depression, consider St. John’s wort [*Hypericum*, which] . . . exerts a potentiating effect on the three neurotransmitters—noradrenaline, serotonin, and dopamine—that are depleted in depression sufferers.

inhale deeply). Cigarettes also contain polonium-210—five thousand times as radioactive as radium, and a common source of local radiation poisoning—from the high-phosphate fertilizers, made from radioactive rock, that are applied to tobacco crops! The tobacco industry knew about this radiation in 1959, but concealed it. Most tobacco isn't organic, so toxic pesticides are also inhaled.

Cigarette filters are made of glass wool (fiberglass), whose needle-like splinters, inhaled into the lungs, tear and scar the tissue. This damage is similar to that caused by asbestos. Tobacco depletes nutrients. The body uses its vitamin and mineral stores to transmute the chemicals into less harmful ingredients.

Inhaling secondhand smoke is even more damaging than directly inhaling from a cigarette. According to a 2014 World Health Organization report, direct *and* secondhand smokers have a 45% percent higher risk of developing dementia and Alzheimer's. Cigarette filters help protect smokers from some of the contaminants; but those exposed to secondhand smoke lack this protection. In some parts of the world, laws have been passed that prohibit smoking in public places. Although these laws seem harsh to some smokers, they help protect the air that we all breathe.

Nicotine is well known for being physically addicting, but there's also a strong emotional component to smoking: many people who quit become depressed. Nicotine causes the brain to create the “feel-good” chemical dopamine, but the body becomes habituated to the nicotine. So, over time, more is needed for the smoker to feel normal. Also, although nicotine initially increases respiration, ultimately it dampens it. Decreased respiration equals decreased awareness of emotions because emotional expression is directly connected to the ability to take full, deep breaths (see the **Bodywork** section later in this chapter). We unconsciously hold our breath when we're depressed, which helps us avoid painful feelings. Thus, the inhibited respiration caused by tobacco ultimately helps us avoid painful emotions. When someone quits smoking, unwanted emotions tend to resurface—which partly accounts for reports of depression in former smokers. It's more empowering to learn to acknowledge, accept, and heal our emotions than to rely on externally administered chemicals that suppress or modify them.

Plain untreated tobacco is less harmful than commercial cigarettes. If you want to smoke, buy organically grown, untreated tobacco and roll your own cigarettes.

Marijuana / Hemp / Cannabis

Like its botanical relatives hops and nettles, *Cannabis sativa* tinctures, teas and powders have been used all over the world for centuries to treat many medical conditions. In fact, in the 1800s and early 1900s, the majority of medicines in the United States were derived from cannabis. Not coincidentally, the entire body contains receptor sites for the herb's compounds or *cannabinoids*. During exercise the body produces beneficial *endocannabinoids*, which are chemically similar to the plant compounds.

When the United States was founded, colonists were legally required to grow hemp, which was used for fabric, rope, paper, fuel, varnish, paint, and edible seeds. Livestock grazed on hemp, and people who ate the animals regularly ingested the cannabinoids. Doctors

legally and routinely prescribed cannabis oil until 1937, when the US government changed the herb's name to “marijuana” and imposed harsh tax laws to prevent it from being freely used. Decades later, marijuana was reclassified as a dangerous drug. Only recently have these laws been relaxed.

There are many different strains of *Cannabis sativa* with different properties and a combined total of no fewer than 483 chemical compounds.

I will discuss two strains.

Marijuana is raised for its *tetrahydrocannabinol* or *THC*, whose psychoactive effects are augmented when the dried herb is smoked (or sometimes cooked and baked into food). The female plant's flowers, buds, and concentrated resins (hashish) are the most potent. *Hemp* refers to cannabis that contains less than 0.3% of *THC* and may or may not contain high levels of *cannabidiol* or *CBD*. Both are therapeutic. After the US government banned cannabis, the plant was selectively bred to *increase* the levels of mind-altering *THC* compounds and *decrease* the levels of healing *CBD* compounds. Now that hemp is again legal in the US (providing it's mostly *THC*-free), cannabis growers are reintroducing the beneficial *CBD* and other compounds via manual selective breeding (not genetic engineering).

Several hundred medical journal articles, some from the 1980s, show that *cannabis* heals not only heart disease but also neurological disorders, including epilepsy, anxiety, PTSD, Parkinson's, and schizophrenia. Just a few titles are: “A Molecular Link between the Active Component of Marijuana and Alzheimer's Disease Pathology”¹⁵¹; “Pathways mediating the effects of cannabidiol on the reduction of breast cancer cell proliferation, invasion, and metastasis”¹⁵²; and “Cannabis in painful HIV-associated

When correctly used, herbs promote the elimination of waste matter and poisons from the system by simple, natural means. They support nature in its fight against disease; while chemicals, not being assimilable, add to the accumulation of morbid matter and only stimulate improvement by suppressing the symptoms.

sensory neuropathy: a randomized placebo-controlled trial.”¹⁵³ Cannabis has anti-tumor activity. It restores appetite, thus preventing people with wasting diseases from starving. It alleviates pain associated not only with cancer, but also Multiple Sclerosis and glaucoma (by reducing excess pressure on the eyeball). And cannabis heals the gut—which has the same receptor sites as those in the brain and is sometimes called “the second brain.”

Truly medicinal marijuana is not smoked. Earlier in this chapter I discussed how fire damages plant and animal products. *Burning cannabis changes the chemical structure of its cannabinoids.* In fact, the hallucinogenic effects of THC are partly due to the augmented acid levels when the plant is burned. Brain chemistry, meridians, and energy fields all become unbalanced. Furthermore, burning the THC reduces other therapeutic effects that it could have on the body. This is why smoked marijuana can produce negative symptoms (especially if THC levels are high): impaired coordination, reaction times and short-term memory; depression, mood swings, paranoia and anxiety; and lowered blood sugar (which induces snacking, usually on carbohydrates, to replenish rapidly dwindling blood glucose levels). Burned pot can increase the heart rate by as much as 50%, and cause chest pain in those whose blood supply to the heart is already limited. Research also suggests that pregnant women who smoke pot may give birth to more premature and low birth-weight infants. Of course, inhaling any burning substance injures the lining of the lungs and produces free radicals in the body.

Medical doctor William Courtney advocates juicing *fresh, raw* cannabis leaves. The compounds in raw juice have anti-inflammatory, analgesic, and immune regulating properties. They improve the efficiency of the cellular mitochondria. They help with waste removal. And they protect the brain and nervous system from degeneration. Deep, permanent healing is reported for a wide range of conditions. It can take four weeks to start seeing results.

Most people cannot obtain raw cannabis, but cannabis *oil* is now commercially available. It's put into salves for skin wounds, inhaled (“vaped”) for respiratory, mental and nervous system disorders (this delivery system gets it into the bloodstream rapidly), and taken orally (ideal for healing the digestive tract). The oil should be organic, free of propylene glycol and other harmful solvents, and properly extracted. In unburned cannabis, the CBD mitigates some of the mind-altering effects of any existing THC. However, mild psychoactive stimulation can still be induced by THC and other similar compounds, all of which attach to the body's endocannabinoid receptor sites. People react differently to different strains.

By the way, drug companies are now applying for—and receiving—patents for medical marijuana.

HERBS

Seasoning or Therapy?

When you hear the word “herb,” it's easy to think about the oregano in your mom's spaghetti sauce and forget the centuries during which humankind used herbs as medicine in thousands of ways.

Cooks use the word “herb” differently than do herbalists. In the culinary arts, a plant's leaves, stalks and flowers are called herbs; and its seeds, bark and occasionally flowers are called spices. Basil, parsley, cilantro and tarragon—all leaves—are herbs. Peppercorns (seeds), coriander (the round seed of the cilantro plant), cinnamon (the bark of a tree), and saffron (the golden orange stigma threads of the autumn crocus) are all spices. When discussing the therapeutic use of herbs, however, I define “herb” as a seed-bearing plant that does not develop woody tissue but dies at the end of a growing season, and which is valued for its medicinal properties. Any part of the plant can be used: stalk, leaf, bud, flower, root, or seed.

How did our ancestors know which plants to use for what ailed them? They observed what plants sick animals ate. To find new remedies, the most experienced users—herbalists or medicine men/women—hiked the outdoors with their followers. When they saw a new interesting plant they'd stop, smell, pick, chew, swallow, and wait to see what the effects were. As you might imagine, this method produced some casualties. Through centuries of observation, treatment and experimentation, humans learned which herbs worked and under what circumstances. Knowledge was first imparted orally, and later careful written records were kept.

Some herbalists classify plants as either medicinal because they are solely used to treat illnesses and chronic conditions, or culinary because they are used as flavoring. However, with these definitions the line between the two groups can be blurry. It's true that some very unpleasant tasting herbs such as goldenseal and valerian root are used solely for medicinal purposes. But other plants used in cooking can be used medicinally, provided they're consumed in sufficient quantities. For instance, turmeric, a root related to ginger—often used in Indian cuisine to impart flavor and a distinctive golden color—has considerable anti-inflammatory properties and inhibits the growth of tumors if used in large enough quantities. Hot peppers, which provide heat, have also been a staple in Indian meals for centuries due to their antiparasitic and antibacterial qualities (a valuable feature in a tropical land where food can spoil easily). And aromatic spices such as cardamom and cinnamon are used not only to make food tastier, but also to foster digestion.

Likewise, in many parts of the world, bitter greens such as dandelions are eaten as salads because they improve digestion by stimulating the liver to produce bile, increasing the production of saliva in the mouth, and encouraging the production of hydrochloric acid in the stomach. Clearly, a much more objective indicator of what constitutes a medicinal plant is needed, as the above considerations seem to depend as much on the intention of the user as on the plant's potency, properties, and amounts used.

The answer to the classification problem—as well as a truer understanding of what herbology is really about—lies in the science of *phytotherapy*, or the pharmacology and medicinal application of plants and their extracts. The practice of phytotherapy is taken so seriously in Australia that herbs are heavily regulated, like drugs. In Australia, an herbologist is called a *phytotherapist*.

Kerry Bone, a well-known phytotherapist in his native Australia, has gained worldwide recognition in the last decade. His outstanding textbook (written with Simon Mills), *Principles and Practice of Phytotherapy*, explains that although many laypeople and even some professionals mistakenly believe that “the various nutrients such as vitamins, minerals, . . . enzymes and other proteins, lipids, carbohydrates and chlorophyll . . . and so on are responsible for the pharmacological activity of plants, . . . almost without exception, this is not the case.” These nutrients—which phytotherapists call “primary metabolites”—are “necessary to sustain the life of the plant”; but it is the “secondary metabolites” that interest phytotherapists the most. Secondary metabolites “do not appear to be necessary to sustain [the plant's] life,” but appear to “have more subtle functions which increase the survival prospects of the plant in its natural environment.”¹⁵⁴ Plant survival mechanisms include the chemicals it produces to defend itself against fungi, insects, and other unique stressors in its environment. Because the phytochemicals protect the plant, chances are they can protect the humans and other animals that eat those plants. It is these chemicals that provide the foundation of phytotherapy, or herbal medicine. (This category does not include toxic compounds that prevent seeds or grains from sprouting.)

The pau d'arco tree in South America is an example of this principle. The bark of the tree has been used medicinally by the Brazilian Indians for over a thousand years, due to its ability to resist rot and fungi in a humid, hot climate. Today, people with *Candida albicans* and other fungal infections make the bark into teas and tinctures to provide enhanced immune function and resistance against yeasts, fungi, and mold.

The displacement of herbs by modern synthesized pharmaceuticals is a recent phenomenon. White willow

bark, which contains salicin, was routinely used for headaches, pain and fever since at least the 5th century BC—until the Bayer Company, in 1897, extracted the salicin and synthesized it into the chemically similar acetylsalicylic acid, otherwise known as Aspirin®. (Aspirin has become so commonplace that the word is now used as a generic term.) *Digitalis latana* (foxglove) was used before we had the chemical digoxin. Opium was smoked from poppies to treat pain before morphine was extracted in 1806, and codeine was synthesized in 1832, from the opium. The powdered bark of the cinchona tree was a popular remedy for malaria until quinine was isolated in 1944. The Pacific yew tree was a folk medication long before the drug we call Taxol® was separated and synthesized from the bark for its anticancer properties. (The drug is not as effective as the herb, as it doesn't contain all the phytochemicals of the bark from which it was derived.)

For centuries in India, the root of the *Rauwolfia serpentina* (a plant in the dogbane family) was taken as a tranquilizer before scientists isolated and extracted specific chemicals to treat hypertension. And witch hazel leaves were made into tinctures and poultices to alleviate congestive blood disorders, long before modern chemists distilled select portions of the plant to obtain the clear liquid we buy today at the drug store.

The list of plant-derived remedies is endless. Mills and Bone conclude, from a review of herbal therapy traditions, that herbal medicines did not target symptoms, but corrected internal disharmonies.

In the absence of modern instrumentation, internal disharmonies were understood as *subjective* matters, often described in climatic or emotional metaphors or by metaphysical constructs [the Chinese] (*yin/yang*, the [Indian Ayurvedic medicine] *doshas*, the [European] humours), that were widely understood among the general population. From the herbalist's perspective, most internal disharmonies involved literal or substantial disruptions in the body . . . [involving] equally the body and the mind (and often the spirit), so that one internal disharmony could affect all planes of experience. *There was no Cartesian [mechanized] body-mind split.*¹⁵⁵

One of the most serious subversions of herbs, resulting from the mechanized body-mind split, is the practice of extracting and isolating the so-called active ingredient from the plant. From the allopathic perspective, it is perfectly reasonable to extract the “active” ingredient from herbs and eliminate all of the “extraneous” parts of the plant that appear to be irrelevant to the effects we want to create. The problem with this mindset is

that these “extraneous” materials are integral to, and synergistic with, the total effects of the plant. The word *synergistic* is from the Greek *synergetikos*, which means “working together, in cooperation.” An herb contains not just the presumably (or only) “active” ingredient, it contains many ingredients that interact with each other as a complex whole, so that the effects of the whole are greater than the sum of its parts.

How does this principle translate to a plant’s effect on people? Consider *Hypericum perforatum* (St. John’s wort), used for its antidepressant effect. When scientists extracted hypericin and pseudohypericin from the plant—the two “active” ingredients responsible for the antidepressant activity—the test subjects were not very successful in overcoming their depression. However, when a third, apparently innocuous compound from the plant (procyanidins) was added to the mix, the total antidepressant activity markedly intensified. Procyanidins do not have any mood altering effect of their own. However, they help the body assimilate the other two substances by making them more soluble. Again, we learn the lesson that the entire plant is needed, although there are some exceptions. See Sidebar, “The Creation of New Herbal Substances.”

The allopathic tendency to isolate from herbs only what it considers useful, causes problems with so-called “side” effects. “Side” effects exist in allopathic medicines because the body is trying to assimilate a “pure”—in other words, fractionated and isolated—chemical. But “pure” chemicals don’t exist in Nature. The phytochemicals in plants exist in a matrix, where they not only complement each other, but in some cases neutralize the negative effects of the other constituents. A good example of this principle can be seen in the effects of aspirin versus white willow, both of which are taken for headache and other pain. Aspirin, the modern pharmaceutical, can upset the stomach. White willow bark does not. Why? The ingredients in the whole plant provide their own checks and balances against harsh effects like stomach upset. Modern pharmacologists, believing that they can improve on natural plants by eliminating all those unnecessary “extra” ingredients except the one chemical “known” to reduce pain, have produced vastly inferior products.

A properly trained herbalist is so aware of the need for checks and balances when dealing with living systems, that not only are the right herbs painstakingly chosen, but combinations of different herbs are also selected very carefully to enhance a desired outcome and mitigate possible unfavorable effects. The holistic approach of qualified herbalists is not antithetical to good science. In fact, the vast knowledge of chemistry required for a professional phytotherapy practice indicates a much

The Creation of New Herbal Substances

There are a few exceptions to the centuries-old tradition of using whole herbs. Sometimes, even without a historical precedent, only portions of plants are used. Take *Ginkgo biloba*, one of the oldest species of trees on Earth, believed to have inhabited the planet up to 150 million years ago. Ginkgo trees can live to be over thousands of years old. The nuts of the tree have been widely used in traditional Chinese medicine for centuries, but no literature exists on the use of the leaves for any purpose.

The high levels of antioxidant flavonoids and terpenoids in the tree—which protect it from oxidative cell damage caused by free radicals—work for humans, too. In the 1960s, German scientists experimenting with a highly concentrated ginkgo leaf extract discovered that it could enhance memory and cognitive function, increase blood flow (in the brain, sexual organs, and other areas), oxygenate the tissues, and even expel intestinal worms. Although the ginkgo leaf extract is standardized for only its major so-called active ingredients—which would appear to place it more in the category of fractionated drug than whole herb—the formula is stable, works well for the desired purposes, and is very safe without “side” (undesirable) effects. Rightly, herbalists see no reason not to use ginkgo leaves.

deeper understanding of rigorous science than is normally displayed by many pharmacists, and certainly most doctors.

Macrobiotics consultant Steve Gagné reminds us that “Drugs themselves...are hyperspecialized descendants of herbal remedies, which themselves are extensions of the healing lore of ancient Food Energetics.”¹⁵⁶ Ideally, we try to use food first to correct an imbalance that creates the need for an herb, although sometimes the most nutritious food cannot nourish us and we need stronger agents to catalyze change. However, herbs should be used with care (although they are far safer than pharmaceuticals). For instance, some herbs should not be used at all during pregnancy. And other herbs that are popularly touted as indispensable and suitable for everyone, may not be: licorice, for instance, is contraindicated for people who retain water. This points to the wisdom of consulting an experienced herbologist unless you have a good grasp of the scientific literature and know what you’re doing.

Some herbalists distinguish between what they regard as “non-medicinal” and “medicinal” herbs. They erroneously believe that “non-medicinal” herbs cause gentle and slow changes and can be used safely on a regular basis, while the stronger, so-called “medicinal” herbs should be used only under certain conditions because they induce the

body to undergo radical changes in a short period of time. These distinctions are inaccurate, though. From the phytochemist's perspective, *all* herbs used for their secondary metabolite properties are “medicinal”—in other words, therapeutic—because they support the body's efforts to restore balance. This is why some phytotherapists refer to an herb as a “biological response modifier.”

Although an herb can act as an agent to transform bodily functions and tissues, if it's properly administered, it creates change without compromising the long-term integrity of the organism. This is in contrast to synthesized pharmaceuticals, which rarely help the body balance itself. So even though phytotherapy is serious science, herbs are not drugs (though they are sometimes used in that way).

That said, a medicinal herb does not have to be used medicinally all the time. Take turmeric and ginger, common in many kitchens. When used in food, these roots are ingested in *seasoning amounts*—although if therapeutic herbs and spices are used often enough and in moderate amounts, there are often therapeutic effects, even if that's not the primary intention for their use. When used to bring someone's system back into balance—for example, if the turmeric and ginger are taken for their anti-inflammatory properties—they are consumed in much larger *therapeutic doses*. When the herbs are used

in slightly smaller amounts to help anchor the changes that occurred during the time the person was on the therapeutic dose, this is considered a *maintenance dose*. During illness, therapeutic doses are administered often. For maintenance, herbs are administered less often. They are used only to sustain the progress made when the person was taking more herb on a more frequent basis.

However, the benefits of some herbs—such as rosemary (for brain function) or aloe's inner leaf (to diminish wrinkles)—actually decrease when they are taken in excess. Some herbs have more exacting levels of optimal effectiveness, and you may require an herbalist's guidance.

Potency and Effectiveness

Despite the centuries-old track record enjoyed by herbs, some people who resonate with holistic healing and have taken herbs for a variety of conditions are disappointed by the results. But this doesn't mean that herbal remedies aren't effective. How the herbs are grown, gathered, and processed affects their potency and effectiveness. Assuming (for the most part) that the person has taken the correct herb, there are many reasons why an herbal preparation might not produce the desired (if any) effects:

A Brief Summary of Essential Oils

Essential oils (from the word “essence”) are mixtures of fragrant compounds which can be isolated from plants by the process of steam distillation. In this procedure, steam is driven through the plant material and then condensed, with the subsequent oil and water phases separating out. Since they are volatile in steam and usually have pronounced aromas, essential oils are often referred to as volatile oils. However, this term is not accurate since they have boiling points well above 100°C [212°F]. Often the oil is slightly modified by the steam distillation process [as well as solvent extraction and dry extraction], so that it does not exactly reflect what is found in the plant. In some cases, such as chamazulene from German chamomile, steam distillation actually produces substantial quantities of a new chemical.

Other processes are also used to produce essential oils and these include [extraction with] solvent . . . [as well as] enfleurage (oil extraction of delicate essential oils in flowers) and expression (used to produce orange and lemon oils from the peel). . . . Essential oils are important items of commerce, being used for perfumes, food flavorings and personal and pharmaceutical products. They also comprise the medicines of the therapeutic system known as aromatherapy [the inhalation of essential oils to enhance mental function, emotional states and physical health].

Essential oils are water-insoluble oily liquids which are usually colorless. Despite the fact that they are called oils, they are not chemically related to lipid oils (fixed oils) such as olive oil, corn oil and so on. . . . They will slowly evaporate if left in an open container and placing a drop of oil on blotting paper can be used as a simple technique to test for adulteration with a fixed oil. If a fixed oil is present an oily smear will remain on the paper a few days later.

Adulteration is an important issue. . . . In some cases, such as oil of wintergreen, trade in the synthetic oil has completely supplanted the natural product. A recent survey found a large variability between the biological activities of different samples of oils and groups of oils under the same general name, including samples from lavender, eucalyptus and chamomile. This reflected on the blending, rectification and adulteration which occurs with commercial oils. Of course, this issue does not apply to oils prescribed as part of the whole plant extract . . .

Essential oils are highly concentrated compared to the original plant [and its extract]. . . . Given the great chemical diversity of essential oils, it is not surprising that they exhibit a wide variety of pharmacological activities.

Principles and Practice of Phytotherapy, 2000

- ◆ A plant is only as potent as the soil in which it's grown. Mineral-deficient soil produces a mineral-deficient plant. This not only reduces the herb's effectiveness and potency, it can even change its appearance.
- ◆ The season and even the time of day or night that the plant is picked helps determine its potency—or even if it's effective at all. This is because the presence or absence of light stimulates or suppresses the plant's production of the desired phytochemicals.
- ◆ Different parts of the plant (leaves, stalks, flowers, buds, and roots) usually have different properties. For example, a label reading “Contains 100% Panax Ginseng” might seem to indicate a high quality product. But only the roots are desirable. If the formula contains worthless leaves, this would impair or even completely negate the overall potency of the formula.
- ◆ For optimal potency and effect, a tincture (liquid concentrate) should be produced from dried herbs, not fresh, because the high water content of a fresh plant (typically, about 80%) will dilute the final preparation and yield a much weaker concentration of valuable phytochemicals, thus lessening the benefits. Also, the naturally occurring enzymes in the fresh plant degrade and deactivate the other phytochemicals. Proper drying of the plant preserves all the constituents intact. Note that some herbal preparations are not usable as tinctures and can only be made into powders. A good example is *mucilaginous* or gooey, water-loving herbs such as slippery elm bark. Because the molecules trap water so easily and swell to many times their own size, it's impractical to bottle them as liquids, because in a very short time they would not be able to be poured.
- ◆ If some plants are dried at too high a temperature, their volatile oils evaporate. Not all herbs are destroyed by intense heat. The phytochemist must know which herbs can and cannot withstand heat.
- ◆ Phytochemicals are either water soluble, fat soluble, or alcohol soluble. Sometimes, different components in the same plant respond to different extraction processes. It's important to process plants correctly so all of the phytochemicals are available to the body.
- ◆ The company that processes the tinctures, and/or bottles and markets the final product, is unlikely to grow the herbs itself or have equipment to test the botanical reliability or potency of the herbs. Therefore, it must accept the supplier's word that the herbs are genuine and contain the desired phytochemicals. If the supplier is dishonest or ignorant, the company has no way of checking. This loss is passed on to the consumer.
- ◆ The herbalist must recommend doses according to the levels of active phytochemicals in the particular plant. Seven to ten grams is generally considered to be a therapeutic dose. If not enough tincture or powder is taken, the desired results won't occur.
- ◆ If an herb is tested in the laboratory, it might work *in vitro* (in the test tube) but not *in vivo* (in a living human or animal body) because the two media usually function in radically different ways. However, the company might still make claims that the herb works.
- ◆ Sometimes plants look virtually identical and grow in the same location, but are actually different plants containing vastly different chemical constituents. For example, goldenseal (*Hydrastis canadensis*)—which is rightly valued for its germicidal and anti-tumor properties—might be substituted with the very different wild geranium (*Geranium maculatum*).

The above factors explain mixed results using herbs. Once I needed white willow bark capsules. Wanting to support a local small business instead of a national company whose capsules I normally used, I bought an unfamiliar tincture. The tincture did nothing except empty my wallet. I threw it away and bought another bottle of capsules from the large company, whose label listed the standardized dosage of “active” ingredients. Unlike the locally produced tincture, the capsules worked.

Another learning experience involved the safety and potency of echinacea. There's a widespread fable that taking echinacea continuously for more than several days is harmful because the herb eventually disables one's immune function, making it impossible for the herb to work later when you “really need it.” According to Mills and Bone, this is a misinterpretation of *one* published clinical study

Gemmotherapy: Stem Cell Therapy From Plants

Gemmotherapy was developed in the 1950s. The term is derived from Latin *gemmae* for “plant bud.” The buds, young shoots, and rootlets of wildcrafted plants—all embryonic tissue—contain the most potent energy and vitality of a plant: nutrients, plant growth hormones, genetic information, and more.

The plants are tinctured and homeopathically potentized. These remedies stimulate the excretory organs (liver, kidneys, skin, colon etc.), and induce gentle, steady drainage. In addition to detoxifying, Gemmotherapy nourishes and rejuvenates. It reverses the effects of aging, increases energy levels, reduces stress, enhances immune response, and improves organ function, gland function, and vision. The tinctures are powerful and inexpensive.

showing that daily ingestion of echinacea did indeed increase the activity level of phagocytes (white blood cells that destroy pathogens and foreign particles). After five days, the test doses were stopped and blood samples were taken immediately. Phagocyte levels remained high for about two days after the echinacea was withdrawn, but then they returned to their former levels. Had the experimenters continued to monitor the blood levels of the test subjects, they would have seen the immune-stimulation effects subside—and presented this data as part of the experiment. The fact that the high white blood cell count remained for two days after the echinacea was withdrawn is a testimony to the herb's effectiveness.

Most tests on echinacea are poorly designed. Sometimes plants with different chemical constituents are used, and treated as comparable when they're not. Some tests use extracts that are diluted but shouldn't be. Also, most research doesn't use oral doses, but injections—which isn't how the herb is taken anywhere in the world. One much-quoted study used healthy volunteers whose immune function was already strong. No increase of white blood cells was noted, so this gave the impression that echinacea doesn't work! Were such "mistakes" deliberately made? Very likely, if the studies were funded by pharmaceutical companies.

For centuries, the Native Americans used echinacea for infections because of its ability to support optimal white blood cell function as well as inhibit the mobility of bacteria. The herb has been used (and can be used) with no ill effects, many times daily during illness, and fewer times a day for maintenance. Throughout the years when I took various brands of echinacea tincture, sometimes I'd notice an improvement in my condition, but other times I would not. It was only after I took a class with phytotherapist Kerry Bone that I learned the key to the herb's potency. Echinacea extract causes the entire mouth to tingle and the tongue to feel somewhat numb. If there's no tingle, the formula's dead.

Herbal preparations should be living, like foods. If you don't see results, you may be using the wrong remedy, or using it incorrectly. Or, the product may not have been made in a way that preserved the effects of the plant. Ask questions about the company's research and potency evaluation facilities. And use herbs with a track record. If the herb is newly discovered, or has been used only recently for a specific purpose, read the scientific literature or talk to someone you trust who has done or read the research.

Just as with foods, certain herbs might be wonderful for someone else but not for you. And different herbs can react with each other—sometimes in beneficial ways, sometimes not. For minor conditions, it might be appropriate to take one or just a few herbs, or a time-tested combination formula from a company with a track record. However, for a serious or chronic condition, see a qualified herbologist who can design a protocol for your unique body chemistry and situation.

"Herbal medicine is not an anachronism practiced by ignorant people. . . . A form of herbal medicine is practiced in every culture and in every country of the world, be it industrialized or not," write Bone and Mills. "Something deep within us recognizes that there is healing power in the plant kingdom which, after all,

is the nourishment of all animal life."¹⁵⁷ The idea that pharmacology can replace plants is not only arrogant, but extremely disrespectful to indigenous cultures. Why does modern medicine believe that it can improve, in one century, what native peoples have been practicing effectively for thousands of years?

Vitamins Prevent Chronic Disease

Most people do not consume an optimal amount of all vitamins by diet alone. Pending strong evidence of effectiveness from randomized trials, it appears prudent for all adults to take vitamin supplements.

NUTRITIONAL SUPPLEMENTS

The nutritional supplements industry has grown rapidly in the last few decades as more people have become health conscious, despite the persistence of negative myths about supplements. The FDA largely claims that we obtain adequate amounts of vitamins and minerals from the foods we eat, yet its suggestions for our "minimum daily requirements" are based on the needs of rats, not humans. Moreover, the medical establishment periodically issues warnings about some vitamins and minerals as though they were drugs. Finally, the public is misled to believe that all nutritional supplements are essentially the same.

As a rule, the body's first focus is on maintaining reproductive ability and short-term health. Only if there are enough nutrients will it then choose cellular repair. Long term diseases, which involve inflammation and oxidative stress, take a long time to develop. They also indicate chronic nutrient deficiencies.

The chronic illness plaguing us worldwide indicates nutrient starvation. Therefore, in this section I will explain what to look for when buying nutritional supplements. First, here's a very brief overview of some basic nutrients.

Basic Nutrients

Vitamins

The word *vitamin* used to be spelled “vitamine.” It comes from two Latin words: *vita* which means “life,” and *amine* to signify an amino acid—because when vitamins were first discovered, they were mistakenly thought to contain amino acids. (Amino acids are the building blocks of protein.) Vitamins are now considered to be co-enzymes because they naturally combine with other substances (such as peptides) to catalyze them to do their jobs. Vital for health, vitamins generally cannot be synthesized by the body and must be obtained from foods.

Minerals

Due to the depletion of our soil, people tend to suffer more from mineral than vitamin deficiencies (except for Vitamin C, discussed shortly). This is especially true of boron, chromium, selenium, and other trace minerals.

The **Water** section at the beginning of this chapter discusses minerals in depth; but a few points are worth reiterating. Mineral salts (*electrolytes*), in proper ratio on either side of a cell membrane, act together like miniature batteries. They regulate the transport of all nutrients into the cell. If the body’s electrical signals are muffled or incomplete, cell functions suffer.

Minerals must always accompany vitamins and other minerals to help maintain systemic balance. One example is calcium, which requires the mineral magnesium to help it across the cell membranes of bones. If not enough magnesium is present, the excess calcium doesn’t reach the bones and instead collects in the soft tissues, causing a type of arthritis. Another mineral, boron, helps with calcium absorption. Vitamin D3 (discussed later as really being a hormone) is also essential for calcium absorption because it promotes the mineralization of bones and prevents them from becoming brittle and deformed. As for calcium, different people require different forms of it (calcium can bind to various elements). Just this example shows the degree of complexity possible with nutrient interactions.

Enzymes

Enzymes catalyze all types of chemical reactions in the body without being destroyed themselves. Although comprised chiefly of amino acids, an enzyme may also contain a single molecule of a mineral (such as copper, iron or zinc) in order to function. “In the 1930’s,” write Sally Fallon and Mary Enig, “when enzymes first came to the attention of biochemists, some 80 were identified; today, over 5,000 have been discovered.”¹⁵⁸ Medical doctor and enzyme expert Edward Howell wrote that what has been

called “vitality, vital force, vital energy, . . . life energy, life and life force” is actually enzyme activity.¹⁵⁹

All enzymatic functions relate to metabolic functions, which are either anabolic or catabolic. During an *anabolic* process, ingredients *combine* to form more complex substances, as in the buildup of muscle tissue. During a *catabolic* process, complex materials *break down* into simpler ones, as when foods are reduced to more basic components. Chiropractor and nutritionist Anthony Cichoke classifies enzymes into six groups, based on the substances they affect and the types of biochemical reactions they induce. Fallon and Enig have a more practical, usable system for the layperson:

Enzymes fall into one of three major classifications.

The largest is the metabolic enzymes, which play a role in all bodily processes including breathing, talking, moving, thinking, behavior and maintenance of the immune system. A subset of these metabolic enzymes acts to neutralize poisons and carcinogens, such as pollutants, DDT and tobacco smoke, changing them into less toxic forms, which the body can then eliminate.

The second category is the digestive enzymes, of which there are about 22 in number. Most of these are manufactured by the pancreas. They are secreted by glands in the duodenum (the upper part of the small intestine) and work to break down the bulk of partially digested food leaving the stomach.

The enzymes we need to consider when planning our diets are the third category, the food enzymes. These are present in raw foods, and they initiate the process of digestion in the mouth and stomach. Food enzymes include proteases for digesting protein, lipases for digesting fats and amylases for digesting carbohydrates. Amylases in saliva contribute to the digestion of carbohydrates while they are being chewed, and all enzymes found in food continue this process while it is mixed and churned by contractions in the stomach. The glands in the stomach secrete hydrochloric acid and pepsinogen, which initiate the process of protein digestion, as well as the intrinsic factor needed for vitamin B12 absorption; but the various enzymes needed for complete digestion of our food are not secreted until further down line, in the small intestine.¹⁶⁰

Enzymes already present in sprouts and in raw and fermented foods help digest those foods. They’re destroyed by heat. Holistic practitioners advise people

who eat cooked food, are ill, or are over 40 years old, to supplement with digestive enzymes.

Functionally, enzymes can be interchangeable. This is why systemic enzymes used for inflammation should be taken on an empty stomach. Otherwise, the activity of the enzymes will be used to digest food instead of scavenge the irritating substances in the bloodstream and tissues that cause the inflammation.

Enzymes are so important to life processes that many practitioners consider supplements mandatory for those with chronic or life-threatening illness. Cichoke writes:

Enzymes can aid digestion, dissolve blood clots, fight back pain, decrease swelling, speed up healing, fight wrinkles, clean surfaces of dirty wounds, help in delicate surgery, ease hindered breathing, stimulate the immune system, and help fight cancer and HIV/AIDS and other viruses. In other words, enzymes can do an awful lot.¹⁶¹

Is it possible to take too many enzymes? “There appear to be no side effects of long-term duration when taking oral enzymes,”¹⁶² Cichoke advises. However, people with clotting disorders, and who are about to undergo surgery, should avoid taking proteolytic (protein-digesting) enzymes, which could thin the blood excessively.

Enzymes are extracted from plants and animal organs. Because they’re more difficult to make than even food-based vitamin supplements, they cost more. In Germany and other parts of Europe, enzymes are the most popular over-the-counter product for relief of pain and inflammation. They work well and cause no “side” effects.

Some enzymes are used to break apart *biofilm*—the sticky, hard, gooey coating secreted by colonies of pathogens to protect themselves from destruction. Most pharmaceutical antibiotics and natural antimicrobials cannot eliminate pathogens hiding in biofilm because the hard shield prevents direct contact. But once biofilm is dismantled, one layer at a time, the pathogens can be destroyed. Some effective enzymes to take for this purpose (on an empty stomach, of course) are serrapeptase, nattokinase, and lumbrokinase.

Essential Fatty Acids (EFAs)

The essential fatty acids Omega 3, 6, and 9 are named according to where the first double bond in their chemical structure is located from the omega end of the molecular chain. EFAs are vital for the development and maintenance of the brain and nervous system. They improve mood and memory, fight inflammation, and support heart health.

EFAs cannot be created by the body (except for a bit of Omega 9), so they must be obtained from food. The relatively unknown Omega 7 is considered “non-essential,”

but it’s also used by the nerve tissue, skin and eyes, and helps burn abdominal fat.

Omega 3 supplements are sourced from either fatty fish (high on the food chain) or shrimp-like krill. Due to severe pollution in our oceans, the larger fish are loaded with mercury. The fish oils should be fresh, and molecularly distilled to remove all traces of heavy metals. The labels will indicate this. Omega 7s can be found in sea buckthorn oil (which causes diarrhea if consumed in excess), and in macadamia nuts and the nut oil (safe). Omega 6s are found in many foods, especially nuts and grains, and can cause inflammation. Most people consume too much Omega 6.

Amino Acids

Amino acids are the building blocks of protein. The body can produce many amino acids from other raw materials, except nine “essential” amino acids that must be obtained from food. Whether you eat animal products (which contain all of the essential amino acids), or foods from the grain or pea/bean/legume group (most of which contain fewer essential amino acids), the body dismantles these proteins into individual amino acids, and then reassembles them to build what it needs: muscle, fascia, skin, hair, enzymes, neurochemicals. The right individual amino acid supplements can safely replace dangerous pharmaceuticals that are taken to presumably balance the brain’s neurotransmitters (see *The Mood Cure* by Julia Ross).

Why We Need Supplements

Our nutrient-depleted soil creates deficiencies in our crops, and then in our bodies. As far back as June 1, 1936, a Mr. Fletcher spoke before the second session of the 74th Congress. His paper, reprinted by the US Government Printing Office in Washington, DC, was known as United States Senate Document #264. It read in part:

Do you know that most of us today are suffering from certain dangerous diet deficiencies which cannot be remedied until the depleted soils from which our foods come are brought into proper mineral balance? . . . Laboratory tests prove that the fruits, the vegetables, the grains, the eggs, and even the milk and the meats of today are not what they were a few generations ago. [They are]. . . now being raised on millions of acres of land that no longer contain enough of certain needed minerals, are starving us—no matter how much of them we eat! . . . A balanced and fully nourishing diet . . . must contain . . . a score of mineral salts. . . 99% of the American people are deficient in these minerals, and that

a marked deficiency in any one or more of the important minerals actually results in disease. Any upset of the balance, any considerable lack of one or another element, however microscopic the body requirement may be, and we sicken, suffer, shorten our lives. . . .

[Charles Northen, MD] made an extensive study of the soil. . . . “Bear in mind,” says Dr. Northen, “that minerals are vital to human metabolism and health—and that no plant or animal can appropriate to itself any mineral which is not present in the soil upon which it feeds. . . . vitamins are complex chemical substances . . . indispensable to nutrition, and . . . [important] for the normal function of some special structure of the body. Disorder and disease result from any vitamin deficiency. It is not commonly realized, however, that . . . in the absence of minerals they [vitamins] have no function to perform. Lacking vitamins, the system can make some use of minerals, but lacking minerals, vitamins are useless. [Plus, the body, when denied minerals, absorbs toxic metals instead.] . . . Our foods vary enormously in value, and some of them aren’t worth eating. . . . For example, vegetation grown in one part of the country may assay 1,100 parts per billion of iodine, as against 20 in that grown elsewhere. . . . Some of our lands, even in a virgin state, never were well balanced in mineral content.”

We must rebuild our soils: Put back the minerals we have taken out. That sounds difficult but it isn’t. Neither is it expensive. Therein lies the short cut to better health and longer life. . . .¹⁶³

Not even a century ago, farmers planted many types of crops. Each plant extracted and returned different minerals to the soil. The soil was further enriched with natural fertilizers. With *monoculture* (single-crop agribusinesses), our soil became exhausted. Synthetic fertilizers were used, causing further imbalances.

There are many reasons to supplement.

Important Features of Supplements

Synthetic, Natural, and Food-Based

As with diet, nutritional supplementation is one of the most heatedly debated topics among health professionals and the aware public. Solid supplements are classified either in the “Synthetic Vitamins Camp” or the “Natural Vitamins Camp.” There are valid reasons to use both. First, however, let’s define some terms.

Synthetic vitamins are created in a laboratory. They are sometimes called “crystalline,” “USP,” or “pharmaceutical grade.” The crystalline powders come from a wide variety of sources (more on this in a moment), and each batch is as uniform as the last. Most of the ingredients may have been subjected to a lot of processing, which may or may not include high heat, chemical solvents, and metal salts that could contain aluminum and lead.

Not all natural vitamins are food-based—in fact, most of them aren’t. So-called natural vitamins are often subject to many different types of processing. The original source materials may have been plants; but they, too, have probably undergone a great deal of transformation. Due to this transformation, despite how they’re labeled by the manufacturers some people regard them as synthetic. At

Nutritional supplements fall into categories, although there can be considerable overlap in function among them.

- ◆ **Detoxification/Cleansing.** The body produces waste materials each day in the course of routine metabolism. Under normal conditions, the kidneys, liver and lymph work hard to eliminate these toxins and require adequate nutrients to do their jobs. When you’re experiencing physical or emotional stress, eating poorly, and/or fighting infection, the body has an even harder time eliminating toxins—which in turn creates more illness and degeneration.
- ◆ **Rebuilding and Maintaining the Body.** While under optimal conditions we need to replenish nutrients daily, our nutritional requirements escalate during illness. Eating organic food and drinking pure water are, of course, important. However, the depleted soil in which our food is grown, along with pollutants in the environment, increases our needs for nutrients even if we have a good diet. Vitamin, mineral and herbal supplements give the body what it needs so we can remain in good health even when we’re aging.
- ◆ **Direct Immune Support.** Immune cells that scavenge pathogens, foreign proteins and bodily wastes may not function well, especially during infection. An analysis of live blood under a darkfield microscope may reveal white blood cells that are sluggish or immobile from the excess waste. Sometimes there aren’t enough immune cells to do the job. Or they might not “remember” how to eliminate pathogens. Colostrum, proline-rich polypeptides, whey, herbs such as echinacea, and various vitamins, minerals and enzymes can all help support immunity.
- ◆ **Pathogen Removal.** Sometimes we need help to kill pathogens. A number of herbs and essential oils eliminate harmful microorganisms while nourishing the body.

the very least, they're in a category between food-based and highly synthesized. The late Abram Hoffer, a Canadian biochemist and psychiatrist who used nutritional therapies for schizophrenia, alcoholism and other conditions, explained on a public forum that "natural" isn't always natural. He was referring specifically to Vitamin C, but his remarks apply to any vitamin that undergoes processing more extensive than simple low-heat drying.

For years I have had patients tell me that they wanted to take only natural vitamins and no synthetics and this is after they had been taking many man made (synthetic) vitamins with success. I point out to them that scientifically the pure vitamins whether made by man (synthetic) or whether made by plants (synthetic as well but made by plants) are identical. . . . Even when nutrients such as vitamins and amino acids are extracted from plants they are no longer natural since they have been made by chemists who grind, mix, extract, purify and crystallize the products using all sorts of chemicals in order to do so, which are then sold as natural.¹⁶⁴

Food-based vitamins, which are minimally processed and fairly "natural" in the common, dictionary meaning of the word, are extracted from vegetables and fruits. The plants are dried and their indigestible fiber is removed. This produces concentrated aromatic powders that are reasonably recognizable as food-based. The powders can either be sold as is, or put into tablets and capsules. Sometimes, food-based nutrients are available as liquids.

The most effective supplements that are made from real foods are dried at exceptionally low heat so that the temperature-sensitive compounds are preserved.

Dangerous Ingredients

The vast majority of companies that manufacture synthetic vitamins use ingredients that belong in the trash and not in our bodies. They're in binders, lubricants, fillers, colorants, and the ingredients that comprise the vitamins themselves. (These substances are also routinely used in virtually every pharmaceutical.)

Binders, which hold the tablets together, often cause allergies. They can also interfere with the body's ability to absorb nutrients. Common binders include starches, sugar alcohols, cellulose, magnesium stearate, polymers (large constructed molecules, usually related to plastic), and partially or fully hydrogenated oils (especially soy). As explained earlier in this chapter, hydrogenated oils (as with all fats) become part of our cell membranes—making them stiff and full of holes, which allows toxins to enter.

Lubricants ("flow agents") coat the tablets, making them slippery so they can be more easily swallowed (while slowing the disintegration of the tablet in the stomach). Magnesium stearate is often preferred, but stearic acid and other starches and waxes may be used too (including, sometimes, carcinogenic talc). Magnesium stearate is also used during manufacture. It reduces friction between the two parts of a capsule when it's being assembled, and prevents capsules and tablets from sticking to each other or to the equipment that's producing them.

Fillers are put into tablets and capsules to take up space—otherwise, the manufacturer fears, consumers might think they're being cheated. Occasionally, fillers such as magnesium stearate (which has many functions) even appear in powder formulas. Another common filler, which adds weight to a product, is silicon dioxide, a quartz-like compound comprised of silicon and oxygen (which also forms much of Earth's crust). Silicon dioxide serves as an anticaking agent too. Vitamin and drug manufacturers equate silicon dioxide with the silicon—sometimes called "organic silica"—that's naturally found in the body and (among other benefits) strengthens immunity, restructures collagen fibers, helps bone and cartilage grow, and is anti-inflammatory. But they aren't the same. Silicon dioxide in your supplement is roughly equivalent to sand.

The safety of magnesium stearate (also called "vegetable stearate") is debated. Not a useful form of magnesium, it may coat the small intestine with a film that prevents nutrients from being absorbed. However, many helpful supplements use this ingredient. Compared to other additives, magnesium stearate may be the least harmful, especially as it's used in such minuscule amounts.

Manufacturers almost always add coloring agents to tablets—presumably to make them more appealing to consumers, to make them easy to identify, and (this is for the manufacturer's benefit) to make it difficult for other companies to copy the pills. Many colors are neurotoxins, such as FD&C Blue No. 2 Aluminum Lake and FD&C Red No. 40 Aluminum Lake (see Appendix F). Titanium dioxide, used to impart tablets with a glossy coating, is a nanoparticle powder known to cause cell damage and cancer (see **Colloidal Silver** later in this chapter).

Some synthetic vitamins contain GMOs, especially if they're made with corn or corn products: citric acid, ascorbic acid (Vitamin C), or maltodextrin and dextrose (sugars). Synthetic Vitamin C is very effective, but a source that isn't corn can be difficult to find.

Coal tar is often used to construct a vitamin. Derived from fossil fuel, coal tar causes allergic reactions and is a well known carcinogen. (It's also used as a base for colorings, preservatives and excipients, which act as

“carriers” for the intended ingredient.) The majority of synthetic vitamins are made from inedible materials. Solid mineral supplements are similarly problematic: many of them are made from oyster shell and rock, which the body cannot assimilate or utilize optimally, if at all.

It’s no accident that these inferior ingredients are so widely used because the manufacturers of synthesized nutrients are drug companies, which produce over 90% of all nutritional supplements on the market.

Co-Factors: In or Out of the Matrix

The Natural Vitamins Camp believes that vitamins, like most herbs, work best when ingested in their original matrix. Vitamins in whole foods don’t exist in isolation; but are accompanied by synergistic substances known as *co-factors* in a *matrix*—and therefore should be taken as food-based supplements only. Co-factors may include antioxidants, trace elements, enzymes, and other substances that activate the vitamin or are activated by it.

One example of a matrix vitamin is Vitamin C. In foods, Vitamin C is accompanied by bioflavonoids: rutin, quercetin, and other components. Another matrix vitamin, Vitamin E—also called *tocopherol*—actually contains *seven* types of tocopherol. The matrix housing the tocopherols includes lipositol, xanthine, and (that’s right, the mineral) selenium, all of which could be considered co-factors of Vitamin E. However, the US government defines Vitamin E as *alpha* tocopherol only, and rates it in strength according to the amount of alpha that it contains.

Does plain ascorbic acid “work”? Yes. According to many medical studies and confirmed by the Vitamin C Foundation, ascorbic acid helps protect the cells and supports a number of bodily functions. Does single-tocopherol Vitamin E “work”? To an extent. However, neither synthetic vitamin is augmented by complementary functions of other ingredients from its matrix.

The Natural Camp considers a synthetic supplement to be a drug rather than a nutrient, independent of its being made from coal tar and other unabsorbed ingredients. “A synthetic vitamin,” states the Organic Consumers Association, “can stimulate a cell’s metabolism, but it cannot upgrade or replace the cell’s components with superior, better quality elements. The results? A degraded cell. [Also,] Nature always packages vitamins in groups. The vitamins work together for better absorption. For this reason, the body responds to an isolated vitamin in the same way it responds to a toxin.”¹⁶⁵ Nutrients in isolation can indeed be an issue. When high doses of single nutrients are taken over long periods, deficiencies of other nutrients can occur. For nutrients to be balanced, all must be available to the cells at the same time.

Product Label from Pure Encapsulations®

Pure Encapsulations® brand produces excellent synthetic vitamins, which makes it popular with both professionals and laypersons. If a synthesized supplement best suits your needs, here’s a good example of what you want to see on the label.

This encapsulated product contains no hidden coatings, excipients, binders, fillers, shellacs, artificial colors or fragrance. Contains no dairy, wheat, yeast, gluten, corn, sugar, starch, soy, preservatives or hydrogenated oils.

Other ingredients [besides the nutrient itself]: hypoallergenic plant fiber, vegetable capsule.

Bioavailability, Analogues, and Molecular Shape

A *bioavailable* supplement is easily absorbed, processed, and utilized by the body. Bioavailability is based both on chemistry and also on the nutrient’s molecular shape. We will use the example of Vitamin C first for this discussion.

People tend to think of Vitamin C as a single entity. However, nutrients exist mostly as compounds, which can assume many forms. Vitamin C consists of an ascorbate ion that’s always bound to something else. That “something else” can be an alkaline mineral ascorbate such as sodium ascorbate, calcium ascorbate, magnesium ascorbate, or potassium ascorbate. It could also be the widely known ascorbic acid, otherwise known as hydrogen ascorbate. The same Vitamin C ascorbate ions are in each compound, which confers the unique benefits of the mineral to which the C ion is bound. Dr. Linus Pauling discovered that of all the four different shapes possible for a Vitamin C compound, only the L-ascorbate form—which can consist of any of these ascorbate ion compounds—is protective *and* helps the body make collagen.

A similar situation exists with Vitamin D. For the purposes of this discussion Vitamin D it has two forms: D2 (*ergocalciferol*) and the biologically compatible, easily stored, more active D3 (*cholecalciferol*). Vitamin D2 is found in some plants. Not being readily available—to such an extent that it can cause harm—D2 is a cheap (and dishonest) way to “fortify” foods so consumers think they’re receiving something of value. Vitamin D3 is found in certain fish, cod liver oil, and dairy. It’s also made by the skin if the host has sufficient exposure to sunlight’s beneficial ultraviolet wavelengths (UV-B).

The molecular structures of various types of the same vitamin (including those made from coal tar) can denote huge differences, even if the structural variations appear slight. A vitamin that’s not bioavailable may contain the

Royal Lee and the FDA

Like his colleague Royal Raymond Rife, Royal Lee was a resourceful inventor (who shared the same unusual first name). He filed over one hundred patents for various electronic equipment (among them the phonocardiograph, and a governor for electric motors). He devised advanced weapons control systems during World War II, assisting NASA with his motor control design for their lunar guidance systems. However, Lee's most enduring and important legacy was for peace, not war: his many devices to extract the nutrients from whole foods without disturbing their molecular structure or energetic integrity. With these inventions, he founded Standard Process, a nutritional supplement company that created high quality products from organically produced vegetables, fruits, nuts, grains, and occasionally animals. "Dr. Lee," one health writer reports, "once said that it took him longer to develop a nutritional formula than to come up with one of his electrical inventions. This was due to the complexity of factors already present in nature. . . . Because Dr. Lee insisted that foods were therapeutic, he was always in court, fighting the FDA which insisted that only drugs could be called therapeutic."¹⁶⁶ One of Lee's most vociferous opponents was AMA publicist Morris Fishbein, who had also persecuted Rife and was pivotal in ruining his career. In *Medical Mussolini*, published in 1939, Morris Bealle recounts, in impassioned (if quaint) language:

Another interesting case is that of the Vitamin Products Company of Milwaukee [now Standard Process], owned by Dr. Royal Lee. This concern manufactures and distributes concentrated or "dried" vitamins—those vitally necessary food elements which "civilized" man cooks or processes out of the whole foods nature gives us. In my own family I have positive evidence of the value of Catalyn®, which is . . . [the primary whole food supplement and the best selling of all] the Lee products.

Dr. Lee was one of those "hardy" souls who refused to pay \$30,000 or any other sum for a "test" of his product. As a result he was made an active member of the Fishbein blacklist. He even rated an excommunication in the *Journal of the AMA*.

In a letter to an inquirer Mr. Fishbein overstepped himself. While unqualifiedly branding the proven product Catalyn® as "a crude piece of quackery," he made the amazing admission that neither he nor his Association have ever made an investigation or chemical analysis of the product. However, his stooges in the Food and Drug Administration made what Dr. Lee describes as an "amateur's test." In a letter to another inquirer, an official of the FDA claimed that a "recent analysis of the preparation showed it consisted essentially of starch, bran, yeast, [natural] sugar and oil." Even this analysis—if it can be called such—showed entire absence of harmful substances, which is the only thing the Food and Drug Administration is supposed to protect the public from. [This was before the law was changed in 1962.]

Dr. Lee points out that a vitamin product can only be tested by a biological or clinical test—not by a microscopic and chemical analysis such as Fishbein's "expert" stooges in the Food and Drug Administration used in aiding him to club off the market an independent manufacturer.¹⁶⁷

same number of carbon atoms as its natural counterpart. But *where* those atoms appear on the molecule can have huge ramifications in a living body. With Vitamins D3 and D2, one must carefully study their diagrams to spot the difference between them. Even the presence or absence of one tiny line, which indicates the displacement of just a single molecular bond, reflects the difference between D3's bioavailability and D2's harm.

Some specifically synthetic vitamins—whose molecular structure makes them similar, but not identical, to their naturally occurring counterparts—are *analogues*. Analogues occupy the receptor sites that ordinarily would accommodate the genuine article. If an analogue usurps enough available receptor site space, it prevents the real vitamin from latching onto the sites and doing its job. One example is synthetic Vitamin E. The synthetic molecule is d-l-alpha-tocopherol, while the naturally occurring molecule is d-alpha-tocopherol (without the "l"). A study,

published in 1998 in *The American Journal of Clinical Nutrition*, found that natural Vitamin E is two times more bioavailable than its synthetic counterpart.¹⁶⁸ One naturopath points out, "Synthetic Vitamin E is made from . . . [chemically synthesized] turpentine. The human body [was not designed] with receptor sites for synthetic products, especially one whose precursor is paint thinner!"¹⁶⁹

(Interestingly, while most nutrient analogues are from synthetic sources, some do exist in food. For example, most seaweeds contain Vitamin B12 analogues that prevent the genuine, usable B12 from occupying its cell receptor sites. Seaweeds contain many valuable nutrients, so if you eat them regularly, take a B12 supplement or eat plenty of red meat several hours away from ingesting the seaweed.)

To the Synthetic Camp, it's not important if a vitamin is an analogue. To the Natural Camp, this fact is significant. In my opinion, bioavailability should matter to everyone.

The Quality of Light

There's one more crucial difference between natural and synthetic vitamins: the energy that they emit on various levels. Although this might at first seem a bit esoteric, it's a real, proven phenomenon that is scientifically measurable.

Discoveries about the energy of nutritional supplements were first made in the 1930s by an American dentist named Royal Lee (who, by the way, was a supporter of Royal Raymond Rife). With the aid of a spectrograph, Dr. Lee assessed foods, food-based nutritional supplements, and synthetic vitamins. The *spectrograph*—first invented in 1876 and today also called a *spectroscope*—is an instrument that separates and measures the wavelengths that are present in the electromagnetic radiation that objects always emit. The wavelengths can be infrared, radio frequency waves, visible light (to name just a few types), which are all part of the electromagnetic spectrum. When analyzing visible light, the spectrograph disperses it into its component wavelengths—in other words, colors. Spectrography can also detect and measure the electromagnetic fields emitted by protons, electrons, and other charged particles in atoms. Charged particles rotate in diverse directions, depending on the substance; and different movements release different wavelengths on the electromagnetic spectrum. All of these electromagnetic emissions are used as a guide to identify the substance. (See Appendix C for more information on the electromagnetic spectrum and its different wavelengths.)

You may recall from Chapter 2 that Royal Rife could see microorganisms through his Universal Microscope because of the way they refracted light (their wavelength). A wavelength or frequency is part of the vibrational signature of an organism. Everything in the world—whether it's a microorganism, person, plant, or vitamin—expresses itself as wavelengths.

As it turns out, Dr. Lee discovered that food grade and coal-tar-fabricated supplements refract light differently. These emissions also correspond to the differences in the molecular structures of synthetic and food-based vitamins, which are often the mirror image of each other. Lee also found that synthetic and food-based supplements possess opposite electrical polarities. A veterinarian explains:

This issue [of polarities] relates to the rotation of the organic molecule. In its natural form the vitamin has a right or left handed rotation. The body's receptors are configured to bind with this specific rotational configuration so that the proper rotation is capable of properly interacting with the appropriate biochemical processes. Vitamins synthesized in a laboratory contain both a right and left handed rotation. The proper rotational

configuration can bind to the appropriate receptor sites while the opposite rotation can not. Therefore only the proper rotation is therapeutically useful as a vitamin. Further, it has been discussed relative to the pharmaceutical industry that drugs are a mixture of both right and left rotations. Only one rotation is clinically useful while *the opposite rotation is associated with the negative side effects of the drugs*. Since synthetic vitamins must be considered drugs we must therefore assume that at least some of the toxic effects of synthetic vitamins are related to this same phenomenon. [emphasis added]¹⁷⁰

Variations in the chemistry of presumably similar vitamins, then, reflect their energetic differences. At one time, Standard Process (the nutritional supplement company that Lee founded) published a spectrographic set of color photos of Vitamin C in its various forms. The photos depicted vitamins synthesized in a lab as well as Standard Process's own food-based supplements. Also photographed were the emissions from fresh oranges and pasteurized orange juice from concentrate. Each photo was different. The one labeled "natural Vitamin C" was much more vibrantly orange, and radiated more symmetrical lines (we must assume, representing life force) than the photo labeled "synthetic ascorbic acid." Even if synthetic and food based ascorbic acid are chemically identical, how important are the other factors? For whom? And when?

A few years ago some salt water fish were brought to a London aquarium, but there was only a small amount of sea water there which was insufficient for the needs of the fish. One of the curators said that he could make sea water, as its formula was well-known. So he got out the book, assembled the ingredients and made a batch of sea water: But when they placed a fish in the water it soon died. Three or four times the curator made sea water, being more careful each time, but the fish that went into the tank, died in every case. There was one smart curator there, who had a brainstorm. Let us take this last batch of artificially-made sea water and put it into the tiniest bit of real sea water. When they did that, the fish could live in it. Evidently in real sea water there is a gleam of some substance which is too tiny to measure and which, therefore, is not in the published formula for sea water, but which is needed by fish in order to live.

Standardized Amounts

The Synthetic Vitamins Camp points out, correctly, that it's much easier to standardize dosages or amounts of synthetic vitamins than food-based vitamins. The same species of plants grown in different locations don't always contain the equivalent nutrients or amounts, because the soils and climates in which they're raised, and even the seasons and times of day during which they're picked, can cause significant variations. This creates a problem with food-based supplements: You can't always be sure that you're getting the desired amounts of nutrients. However, weights and amounts can be precisely calibrated in a lab.

Many people are surprised to know that US law requires the manufacturers of *all* vitamins, even food-based ones, to put at least some amount of laboratory-synthesized vitamins into their products. This is done to increase their potency and/or stability, and especially to standardize the amount of nutrients per capsule, tablet or batch. The doses must be consistent; otherwise, the product labels would be meaningless and people wouldn't know how much of each nutrient they're getting. When you're dealing with a deficiency especially, it's critical to know exactly what, and how much, you are ingesting. Therefore, every food-based supplement that's legally sold, which states "this bottle contains this amount of such-and-such," has added a nutrient created in a lab.

Don't be fooled by the word "natural." As Dr. Hoffer once posted, this "is a play on words and allows the producers to charge more for the item. If natural vitamin C products contained 90% synthetic ascorbic acid and they add 10% dried rose hips powder, this allows the label to use the word 'natural'; but the honest manufacturer will in small letters at the bottom add 'plus ascorbic acid.'" ¹⁷¹

Even though most (or all) food-based supplements contain added synthetic vitamins and/or minerals, these amounts are minimal. They don't substantially affect the living quality of the rest of the nutrients, and are unlikely to hurt you.

Fat-Soluble or Water-Soluble

Vitamins are dispersed by either water or fats. Fat-soluble vitamins (A, D, and K) remain in the fatty tissue for long periods, while water-soluble vitamins (B-complex and C) are excreted in the urine if the body doesn't use them immediately. Therefore, they must be replaced daily. Even with storage of a fat-soluble vitamin, though, you may still need high amounts. For instance, a naturopath told me that many of her clients with liver damage had a deficiency in Vitamin A. In this case, for a circumscribed period of time, taking more than what's considered the maximum dose is just what they needed. Then there was a woman I knew who had suffered excessive respiratory

problems for an entire year. Each day, she took many hundreds of times the recommended daily dose of Vitamin A because it helped her. When she decreased the amount, her respiratory symptoms came back. Obviously, her body needed all that Vitamin A that she was taking; otherwise, she would have manifested symptoms of excess. Regarding water-soluble vitamins, some sources have reported that too much ascorbic acid can concentrate and recrystallize in the urine, forming sharp little ascorbic acid spikes that irritate the delicate membranes and cause urinary tract infections. I have no way of verifying whether or not this is true. My point is, anything can be consumed in excess; so check with your health care provider if you have questions about the amounts of supplements that you're taking.

Minimum Daily Requirements

How much of a given nutrient do we need daily? The FDA has set standards for "minimum daily requirements" and "maximum daily requirements." But when offering recommendations, the US government generally applies the amounts needed by chicks, rats or rabbits to human beings. Even if it did not, our depleted soil and polluted world render these guidelines meaningless—and even harmful, if people believe what they are told.

Brian Clement, author of *The Vitamin Myth*, states:

Taking synthetic vitamins in milligram quantities is related to the RDA's (Recommended Daily Allowance) or the more modern RDI's (Recommended Daily Intake), but this still does not actually relate to potency because potency of a vitamin has to do with its effectiveness and assimilation not its weight. Weight and potency, in this case, are two different things. Naturally occurring whole complexed vitamins from foods created by nature are more "potent" per milligram than synthetic fractions of those vitamins because it is the whole, real vitamin that the body requires, not a synthetic chemical substitute of a fraction of a vitamin . . . So, the quantity of vitamin milligrams is not as important as the quality of the vitamin milligrams. Many vitamin supplement brands play the "milligram game" which is often confusing to the consumer. The idea of "more is better" works fine for some things, but not for toxic synthetics. . . . The important first question should be whether or not the vitamin is natural . . . and not how many milligrams are available. . . . You get more nutrition from a lower number of milligrams when the vitamin is a whole naturally occurring complex from real food. ¹⁷²

Nutrient Conversion: Beta-Carotene, Folic Acid, and Other Lies

The Lie, in One Sentence

People are often told that two different forms of a vitamin, or even different substances, are equivalent to each other and are interchangeable—when they're not.

Vitamin A vs. Beta-Carotene (Active vs. Inactive)

Beta-carotene is a member of the carotenoid family—naturally occurring red, orange and yellow pigments in plants that give some fruits and vegetables (such as carrots) their vibrant colors, and which make green leaves even darker (the green chlorophyll masks the reddish pigments). Beta-carotene exists only in plants.

A related but not identical nutrient, Vitamin A, is a generic term for a number of fat-soluble retinoid compounds (retinol, retinal, retinoic acid and others) obtained solely from animal products: meats (especially liver), egg yolks, raw grass fed dairy (especially butter and cheese), fish, chicken, and turkey. Vitamin A is used to maintain many body functions, including good vision, lubrication of mucous membranes, strong hair and nails, optimal development of the teeth and bones, a strong immune function, the proper formation of proteins, clear skin, and normal cell growth. This vitamin is so important that a deficiency can cause birth defects. Like beta-carotene, Vitamin A can also act as an antioxidant, which helps protect cells from damage caused by free radicals. Most Vitamin A is stored in the liver. Because 5% of the body's stores are used each day, the vitamin must be replaced on a regular basis.

Once ingested, beta-carotene can be converted into Vitamin A. However, many scientific studies show that this conversion is impaired to some extent in almost half the population. For people with exceptionally severe impairment, the conversion rate fails between 70% and 90%. Even when the amount of beta-carotene in the bloodstream triples in conversion-impaired people, there is no rise in Vitamin A levels. The conversion mechanism is unknown, but scientists do know that people with hypothyroidism have a very difficult time converting. Beta-carotene is a *precursor* to Vitamin A.

Even in those who can convert beta-carotene into Vitamin A, the benefits are not optimal. According to the Food and Nutrition Board of the Institute of Medicine, every 12 mg of beta-carotene that's ingested yields the equivalent of only 1 mg of Vitamin A.

Vegetarians often promote beta-carotene instead of Vitamin A—undoubtedly because they don't want people eating animals to obtain their nutrients. But to claim that these two substances are identical, and that it doesn't matter what form you use, is simply untrue.

Vitamin B12: ***Methylcobalamin vs. Cyanocobalamin*** (Active vs. Inactive)

For the purposes of this discussion, there are two main forms of Vitamin B12. *Methylcobalamin* naturally exists only in animal products—particularly shellfish, finned fish, beef liver, red meats, raw dairy (including whey), eggs, and poultry, although nutritional yeast contains a little bit as well. This form is bioavailable to a living body (unless the person has some unusual problems). *Cyanocobalamin* doesn't exist any place except in a laboratory. A completely synthetic preparation, it must be manufactured. Not surprisingly, the synthetic form is more commonly used in nutritional supplements because it's cheap and easier to obtain. But there is a world of difference between the two—both in their molecular structure and in how they affect the body. (Hydroxocobalamin—a synthetic, usually injectable form of Vitamin B12—is occasionally used by health professionals for some conditions such as methylfolate excess, but it's rare, so will not be discussed here.)

The chemical difference between the real (methyl) and fake (cyano) forms of B12 can be seen in a portion of the molecule. *Methylcobalamin* contains a *methyl* group (carbon and hydrogen). *Cyanocobalamin* contains a *cyanide* group. Cyanide is a poison in large enough quantities. Although the amount of cyanide in fake B12 is minuscule and fairly harmless, it must still be excreted from the system. People who are ill don't need this extra burden of eliminating yet one more toxin.

Even more important, in most people the methyl (real) form is better absorbed than its counterpart. It remains in the body for a longer period of time. It benefits the vision, whereas the cyano (fake) form does not. Moreover, the fake form of B12 is *inactive*. It must be converted by the body—via a complicated, multi-step process—into the real, *active* form of B12 in order to be utilized. Not everyone can make this conversion.

Methylcobalamin has many uses. It's a potent antioxidant. It's used extensively by the liver, brain, and nervous system. It's needed for the synthesis and secretion of the sleep hormone melatonin, which helps normalize circadian rhythms (the 24-hour clock), improves the quality of sleep, and lessens the amount of sleep that's needed. This real B12 also works synergistically with real Vitamin B6 to metabolize homocysteine. When B12 levels in the body become low, a toxic amino acid called homocysteine builds up. (High homocysteine levels have been linked to an increased risk of Alzheimer's, heart diseases, chronic fatigue syndrome, fibromyalgia, and Multiple Sclerosis.) Only real B12—

along with another B vitamin, methylfolate (or B9, next column)—is capable of converting this undesirable homocysteine into beneficial methionine.

A B12 deficiency can be experienced as numbness, tingling, burning, lessened or complete loss of sensation, chest and nerve pain, muscle cramping, confusion, memory loss, and slow reflexes. Methyl B12 is best absorbed in the small intestine, so supplementing with probiotics and/or taking B12 sublingually or via injection, is often suggested by experienced holistic practitioners. Estimates show that about 40% of the population is deficient in B12!

Remember the prefix “methyl” in *methylcobalamin*. That “methyl” is critical to understanding how the body works and knowing the best nutrients to give it.

Vitamin B6:

Pyridoxal 5-Phosphate (P-5-P) vs. Pyridoxine HCl (Active vs. Inactive)

There are several forms of Vitamin B6, but the two most well known are Pyridoxal 5-Phosphate (also known by its abbreviation, P-5-P) and pyridoxine (also called pyridoxine HCL). P-5-P is biocompatible with a living body, well absorbed and ready to work immediately—the substance that the body actually uses for at least 100 different chemical reactions per minute. Pyridoxine, the easy-to-make, cheap B6 that’s put into most supplements, is not biocompatible. It must be converted into P-5-P by the liver (with the help of enzymes that require Vitamin B2, zinc and magnesium) before it can be active in the body. Not surprisingly, some people cannot make this conversion well, if at all, especially if the liver is already burdened. Also not surprisingly, the active Pyridoxal 5-Phosphate is ten times more effective than pyridoxine. In unsuccessful or inefficient converters, high doses of the fake B6 can cause numerous problems, including numbness and tingling in the arms and legs.

Among other functions, Vitamin B6 is needed for the metabolism of amino acids and carbohydrates, the synthesis of heme (the iron-containing portion of red blood cells that carries oxygen), the creation of neurotransmitters (including serotonin, dopamine and GABA), the formation of collagen, proper immune function, efficient digestion, and the reduction of inflammation. Deficiency symptoms include nervousness and depression, fatigue, skin problems, abnormal sensitivity to sound, water retention, impaired immune function, nausea and vomiting, muscular weakness, low blood sugar, and susceptibility to injury. A P-5-P deficiency also leads to decreased Vitamin B12 absorption and elevated homocysteine levels.

Anyone can be susceptible to a P-5-P deficiency: infants, pregnant and nursing mothers, the elderly, vegans and vegetarians, people with a poor diet, and

women taking synthetic estrogen in the form of oral contraceptive pills or hormone replacement therapy. Pyridoxal 5-Phosphate is the only form of B6 that gestating and newborn babies can use. Studies show that if fake B6 is given to premature babies—who are more susceptible than full-term infants to SIDS (Sudden Infant Death Syndrome)—irreversible central nervous system damage can result. The real Vitamin B6 works synergistically with the real Vitamin B12 to metabolize homocysteine into methionine (discussed next).

Vitamin B6 cannot be made by the body. It must be obtained from either food or nutritional supplements. An eclectic assortment of foods contains B6: sunflower seeds, pistachio nuts, sweet potatoes, tuna, salmon, poultry, white potatoes, prunes, beef, bananas, pork, avocados, and spinach.

For many people, supplementing with Vitamin B6 is necessary even if their diet includes the above foods. The reason for this is explained directly below. When taking a nutritional supplement, make sure the label reads “Pyridoxal 5-Phosphate” or “P-5-P.” It makes absolutely no sense for anyone to take inactive pyridoxine, which is the fake, unavailable form of B6.

Vitamin B9:

Methylfolate vs. Folate vs. Folic Acid (Active vs. Conditionally Active vs. Inactive)

The Differences. Technically, both folic acid and folate are Vitamin B9, although this name is rarely used. Although used interchangeably—in language usage as well as nutritionally—there are significant differences between them. Folate is naturally occurring in foods, and folic acid is synthetic. I’ll get to methylfolate (the ultimate and best utilized form of folate) in a moment.

Folate, first discovered in green leafy vegetables, was named after the word “foliage.” Vegetables and fruits rich in this nutrient include spinach, kale, beet greens, citrus fruits, tomatoes, avocados, bananas, asparagus, turnips, broccoli, carrots, cantaloupe, and Swiss chard. Black-eyed peas, and pinto, navy, kidney and lima beans also contain folate, as do many whole grains. However, some animal foods, such as beef, lamb, chicken and salmon, and the organ meats liver and kidney, are also very high in folate.

Folate is rightly regarded as a primary nutrient for the brain. It plays a key role in the synthesis of certain biochemicals that allow critical biological functions to occur. Some of the biochemicals that folate helps produce are brain *neurotransmitters*, which govern virtually everything related to the brain: learning, cognition, behavior, memory, sleep, muscle movement, mood, and emotions. When folate levels are low, neurotransmitter levels are low. Depending on which neurotransmitter is low or absent, this can result in

anxiety, depression, irritability, confusion, memory loss, insomnia, addictions, abnormal mood swings, learning disorders, mania, and more.

For decades, folic acid has been put into nutritional supplements because it's cheap and easy to manufacture. Pregnant women are commonly advised to take supplemental folic acid to prevent birth defects. If the fetus lacks folate, it might have missing parts of the brain, missing or incompletely formed skull bones, or the lack of closure of the spinal column. It's laudable that a deficiency condition is recognized by even mainstream medicine—but is the answer to this potential defect really folic acid supplementation? No! If a vitamin supplement label reads “folic acid,” the body is being given a biologically incompatible chemical that may be difficult (if not impossible) to convert to a usable form.

Is the solution, then, to take folate? No again! There's an additional, somewhat complicated piece to this situation. Even if natural folate is taken—either from foods (such as leafy greens) or in supplement form (the label will read “folate”)—the body may still have a difficult time utilizing it. This is because folate (either from the diet or from a food-based supplement) must always be converted by the body into the *methyltetrahydrofolate* form (sometimes called *5-methyltetrahydrofolate* or simply *methylfolate*). This is what the body actually ends up using because it's bioactive. But sometimes the body can't create this form, no matter how good the raw materials are.

The MTHFR Malfunction. Researchers have found that nearly half of the population cannot convert *either* folic acid *or* folate into methyltetrahydrofolate. These individuals carry, from birth, one or two gene mutations. A copy of this mutation from one parent reduces the ability to convert either folic acid or folate to methyl folate by 40%. A copy from both parents reduces this conversion ability by 70%. Even in those who are able to make the conversion, aging makes the conversion increasingly difficult.

The gene mutation that's responsible for this conversion malfunction is *methylenetetrahydrofolate reductase polymorphisms*, called simply *MTHFR*. These initials are also used to describe what this mutation does. I will explain it as simply as possible:

- ◆ *Methylenetetrahydrofolate reductase (NAD(P)H)*—or its shorter and more commonly used name, *methylenetetrahydrofolate reductase*—is the name of the *enzyme* that converts both dietary folate and synthetic folic acid into the biocompatible end product nutrient *methyltetrahydrofolate* (*5-methyltetrahydrofolate* or *methylfolate*) that the body actually uses.

- ◆ The enzyme that transforms folate and folic acid into the usable, biocompatible methylfolate form is created by what is known as the *MTHFR* gene.
- ◆ Half the population suffers from an error in the DNA of the *MTHFR* gene. This error is called a *polymorphism*, which in this context means an *undesirable dual shape*. The altered shape of the *MTHFR* gene causes the production of a misshapen enzyme. This alteration in the enzyme's shape means that the enzyme's function is either impaired or the enzyme is completely inactive.
- ◆ As a result of this misshapen enzyme mutation, the final product—methylfolate—cannot be produced. Without this ability to process a vital nutrient and use it to create critical biochemicals, people with the *MTHFR* mutation generally lead poor quality lives and suffer from many more chronic and infectious diseases than their counterparts who do not have this mutation.

The Methylation Cycle and MTHFR Health Issues.

What are some of the health challenges that arise from the *MTHFR* malfunction? Naturopath Ben Lynch, who has extensively researched (and treats) the *MTHFR* disorder, relays a dizzying list of conditions on his website, *mthfr.net*. Besides cancer, he mentions pulmonary embolisms, fibromyalgia, autism, asthma, schizophrenia, severe depression, infertility, miscarriages, and even cleft palate. These symptoms may seem unrelated, but once you understand how methylfolate works in the body and the amazing number of functions for which it's responsible, the list makes a great deal of sense. I have already mentioned that methylfolate helps create valuable brain neurotransmitters. But, as its name suggests, methylfolate also plays a major role in the complex array of biochemical processes called methylation.

Simply put, *methylation* is a process whereby small chemical compounds critical to health are moved around in the body to where they are needed, for the purpose of generating specific reactions. The *methyl group* under discussion here consists of a single carbon and three hydrogen groups.

Sometimes, health practitioners use the phrase *methylation pathway* or *methylation cycle*. This is a biochemical process that directly manages, or contributes to the management of, a broad range of bodily functions, after the pathway is catalyzed by an enzyme. Methylation occurs at the DNA level. Some of the functions involved with methylation include energy production, immune function, detoxification, inflammation control, and mood balancing.

Many things can go wrong during methylation. For instance, with a process involving nine steps of

biochemical reactions, the first four might be activated correctly. But then the fifth step might not occur, which skews the subsequent reactions. Or, the timing might be off. All of the steps might take place correctly, but in the wrong order: one, two, three, four, seven, five, twelve, etc. Biochemistry is like baking a cake. Add an ingredient at the wrong time, fail to blend it well, or heat it at the wrong temperature, and you get poor results (and an inedible cake). Enzymatic reactions require a precise sequence of specific biochemicals, which are designed to interact with each other at a specific time. If the sequence, biochemicals, or timing are off, you won't get the desired results.

Substitute the phrase "methylation cycle" with "proper enzyme function," and you'll have a clear idea of what can go wrong. People whose diets are poor, who are under constant or high levels of stress, and who don't get enough sleep, all have methylation difficulties. Impairment in the methylation pathways directly impacts immune function, which in turn gradually impacts the function of various organ and endocrine systems. The kidneys, pancreas and adrenals—and their corresponding tasks of toxin and mineral filtration, insulin production and abnormal cortisol levels—malfunction over time. And that's just the beginning. Without the ability to methylate properly, one cannot make glutathione, which helps the liver detoxify toxic substances. There will be problems converting the thyroid hormone thyroxine (T4) into liothyronine (T3), which is the form of the hormone that actually gets into the cells where it's needed. And the body will have difficulty repairing and regenerating tissues.

One job of methylfolate in methylation is to help convert the inflammatory compound homocysteine into beneficial *s-adenosylmethionine*—popularly known as SAME. SAME helps regulate more than 200 enzymes in the body. When these enzymes are working properly due to adequate SAME levels, so does the body. The DNA is protected against damage from pathogens, heavy metals and solvents.

With adequate SAME, there is also less inflammation in the body and better immune function. This is because the SAME that's produced during methylation helps break down histamine. *Histamine* is a compound involved in immune and inflammatory responses. It's produced by the body in response to a foreign substance that the body perceives as an invader. An invader can be a pathogen, the toxic wastes produced by that pathogen, a particle of protein in other types of waste, or (if the body isn't working correctly) even a food. It's histamine's job to make the capillaries more permeable so that white blood cells can flow to the afflicted tissues. While some histamine is helpful—you want white blood cells to easily reach a targeted area

so pathogens can be neutralized and eliminated—too much histamine can cause flu-like or allergy symptoms, such as sneezing, hives, and a runny nose. You want histamine to be produced and utilized under the proper conditions, not for every particle of protein (such as food) that the body *mistakenly* perceives as an invader. (Hence, the development of *anti-histamine* drugs, which help alleviate the symptoms of itchy eyes, copious mucus flow, rash, etc.) If there's not enough methylfolate in the body to produce SAME, there will be too much histamine in the blood.

Again, inadequate amounts of SAME means an impairment or outright halting of methylation. The methyl group, consisting of the single carbon and three hydrogens, won't be present to attach themselves to enzymes and give them accurate instructions.

The methyl group donated by SAME to important enzymes also helps produce a substance called *phosphatidylcholine*. Phosphatidylcholine is critical to the brain and nervous system. It gets incorporated into the structure of the cell membranes. (A strong cell membrane allows nutrients into the cell and encourages the removal of wastes, whereas a weak cell membrane invites toxins in rather than nutrients.)

Phosphatidylcholine is also a source of *choline*, which the body uses to transport fat out of the liver, and to synthesize the neurotransmitter *acetylcholine*.

So, decreased levels of SAME also mean a deficit of phosphatidylcholine, which means a clogged liver, and hence a less efficient transformation of toxins. A deficit of phosphatidylcholine—"brain food"—is the reason for increased risks of autism and Down syndrome.

We must consider yet another factor in this complex scenario: how well the thyroid is functioning. Dr. Lynch has observed that people with hypothyroidism (thyroid underactivity) tend to have sluggish MTHFR enzymes, even if they do not have the genetically-based MTHFR polymorphism. This is because the thyroid hormone thyroxine helps produce the active form of Vitamin B2, *FAD* (acronym for *flavin adenine dinucleotide*). The body cannot use Vitamin B2 at all unless thyroxine converts it into *active FAD*. Not surprisingly, the MTHFR enzyme must have plenty of FAD in order to function. If thyroxine levels are low because a sluggish thyroid is not making enough thyroxine, the MTHFR enzyme will be sluggish too. This leads to low methylfolate levels. As we have seen, low methylfolate levels equals low SAME levels—and all the health problems just described.

One more piece of this thyroid puzzle is that methylfolate is also needed to help convert tyrosine into active thyroid hormone. Because an estimated 50% of the population is hypothyroid (underactive), this makes the methylfolate issue even worse! All of these factors point to an even greater need to pay attention to

thyroid function. In the United States, it's common to get a prescription for natural thyroid supplementation from a medical doctor. In Europe, it's more common to first fix the adrenals (which often fixes thyroid sluggishness), and supplement with nutrients. Dr. Richard Loyd has found that eliminating pathogens (especially parasites) may make adrenal support unnecessary.

The last problem from faulty MTHFR function is the buildup in the bloodstream of *homocysteine*—a peculiar compound that must be converted by the body into more useful biochemicals. Normally, homocysteine is converted into *methionine* (an essential amino acid) or *cysteine* (another amino acid), with the excess excreted in the urine. This conversion is done with the help of (the real) Vitamins B6 and B12. Among other functions, methionine is used by the body to make proteins, convert one form of estrogen into a more usable form, help the liver process fats, reduce inflammation, and utilize antioxidants. Also, methionine is converted by the liver into SAME. However, with a malfunctioning MTHFR, elevated levels of homocysteine build up in the blood. This leads to increased risk of cardiovascular problems (including coronary heart disease, arteriosclerosis and high blood pressure), and a higher probability of dementia, mental retardation and seizures—not to mention all the aforementioned problems that arise when not enough SAME is present.

Correct Supplementation for Methylation Issues.

Below is a compilation of suggestions from methylation doctors, including Ben Lynch and Amy Yasko, to correct the MTHFR methylation problem.

People with any MTHFR issue should *not* take folic acid. Like a stranger looming at your front door and preventing you from stepping inside your house, folic acid attaches to the receptor sites of cell membranes and blocks the beneficial methylfolate from entering the cell. High levels of the toxic folic acid will remain in the blood of an MTHFR individual.

Folate—whether as a nutritional supplement or food—is not advisable either, because the folate is not easily converted. This doesn't mean that you should avoid leafy greens, though; they contain many valuable nutrients and fiber. But for those with MTHFR mutations, even ingesting too much “natural folate” from food can be detrimental unless the end forms of other nutrients (including methylfolate) are taken.

To bypass MTHFR problems, some supplements provide the *end product* of the conversion process: 5-methyltetrahydrofolate or methyltetrahydrofolate, also simply called methylfolate. This is usually taken with two other B Vitamins, which help the body utilize it properly and offer protection from potential toxicities. General dose guidelines from Lynch and Loyd are:

- ◆ (a) 1 mg (1000 mcg) of methyltetrahydrofolate in the morning. The label should read, “5-MTHF,” “5-Methyltetrahydrofolate,” “Methylfolate,” or perhaps “Metafolin®.” (Loyd finds that about 30% of his clients need this extra methylfolate.) Signs of too much methylfolate include headache, migraines, palpitations, muscle and joint pain, and rashes, and sometimes raised norepinephrine levels that cause insomnia, depression, irritability, and anxiety. To reverse methylfolate toxicity, take 50–100 mg of time-release niacin. (Excess methylfolate means more SAME. SAME breaks down niacin, so the excess SAME will be quenched if you take niacin.) Take 250 to 500 mg of curcumin to quench inflammation. Some people also take 2 mg of hydroxocobalamin.
- ◆ (b) 3 mg (3000 mcg) of *active* Vitamin B12, in the morning. The label should read, “Methylcobalamin.” Real Vitamin B12 works synergistically with real Vitamin B6 to metabolize homocysteine into methionine.
- ◆ (c) 50–100 mg of *active* B6, in the morning. The label should read, “Pyridoxal 5-Phosphate” or “P-5-P.” Real Vitamin B6 works synergistically with real Vitamin B12 to metabolize homocysteine into methionine. It also helps the body neutralize and excrete any excess folate *and* folic acid that might be in the body. Not everyone requires this, so consult a practitioner.

Other Protocols for Proper Methylation. A healthy diet is mandatory. Good fats include coconut, avocados, olive oil, raw grass fed butter (if tolerated), and especially the fats in pastured eggs and grass-fed beef. Gluten impairs folate conversion, thus robbing the body of energy.

Some practitioners advise glutathione and probiotic supplementation, along with antioxidant, adaptogenic herbs such as rhodiola, ashwagandha and holy basil. *Adaptogenic* herbs don't stimulate or suppress, but rather, regulate and normalize. Activity that's too low is raised, and activity that's too high is lowered.

Adequate sleep, stress reduction, and moderate exercise are advised, as are thyroid and adrenal support. Evidence also suggests that Lyme disease plays a role, and that once Lyme is eliminated in an infected person, folate conversion will no longer be an issue.

Some laboratory blood tests detect unmetabolized folic acid. However, many people can determine through empirical observation that the unpleasant symptoms they are experiencing are due to an inability to produce methylfolate. Nearly half of the population has MTHFR issues, so there's a 50% chance that you, or someone you know, has this conversion malfunction. If you take methylfolate and its co-nutrients and you feel better, then you are right.

Nevertheless, while whole food supplements may be better theoretically, sometimes synthetic nutrients are preferable—especially for deficiencies that have been occurring over a long period. A few brands of good synthetic supplements are made with safe ingredients. If you have a serious health problem and suspect nutritional deficiencies, consult a holistically-oriented nutritionist, osteopath, naturopath, or other practitioner to help you devise a custom protocol. Some chiropractors have special training in nutrition and muscle testing, and can tell you instantly in the office what you need, and how much.

Conversion Difficulties

A surprisingly large number of people have genetic errors (or, more euphemistically, “variations”) that prevent them from converting certain nutrients, even those in foods, into what the cells can actually metabolize. The prior Insert, “Nutrient Conversion: Beta-Carotene, Folic Acid, and Other Lies,” gives examples of some vitamins that are completely, partially, or not at all bioavailable.

There’s one genetic quirk that all humans share, however: the inability to produce Vitamin C in the body. A 2003 *Nutrition Journal* article explains.

Ascorbic acid is widely distributed in fresh fruits and vegetables. It is present in fruits like orange, lemons, grapefruit, watermelon, papaya, strawberries, cantaloupe, mango, pineapple, raspberries and cherries. It is also found in green leafy vegetables, tomatoes, broccoli, green and red peppers, cauliflower and cabbage.

Most of the plants and animals synthesize ascorbic acid from D-glucose or D-galactose. A majority of animals produce relatively high levels of ascorbic acid from glucose in [their] liver.

However, guinea pigs, fruit eating bats, apes and humans can not synthesize ascorbic acid due to the absence of the enzyme L-gulonolactone oxidase. [The gene in humans to produce this enzyme is non-functional.] Hence, in humans ascorbic acid has to be supplemented through food and or as tablets. . . . Synthetic ascorbic acid is available in a wide variety of supplements viz., tablets, capsules, chewable tablets, crystalline powder, effervescent tablets and liquid form. . . . There is no scientific evidence to show that even very large doses of vitamin C are toxic or exert serious adverse health effects.¹⁷³

Animals whose bodies possess the enzyme to produce ascorbic acid, do so at the rate of 250 mg to 500 mg

per hour, every day. These animals aren’t susceptible to scurvy, anaphylactic shock, pulmonary tuberculosis, viral leukemia, and other conditions. But humans (and primates and guinea pigs), who cannot produce ascorbic acid in their bodies, are. To get enough ascorbic acid comparable to the serum levels in other species—enough to avoid illness—we must ingest it.

The Natural Camp believes that if Vitamin C is ingested in whole foods (or food-based supplements), it doesn’t take much of the vitamin to prevent illness. For some people, raw, living juices and high-energy foods are enough. However, a severe deficiency suggests the need for Synthetics. For those who have suffered from severe deficiencies for a long time, or persistent serious conditions, food-based supplements are inadequate and synthetic Vitamin C supplementation is necessary.

Liquid Supplements

With solid supplements (powders and pills), powders mixed in water are the most easily absorbed. Capsules are somewhat easy, and tablets can be difficult. Hydrochloric acid in the stomach is needed to dissolve solids; so if your stomach doesn’t naturally produce enough acid, you can always take a hydrochloric acid supplement—perhaps with a broad range of digestive enzymes and even ox bile if your digestion is especially poor. To make supplements easier to absorb, open the capsules and sprinkle the contents on food or in liquid (but don’t do this with hydrochloric acid, which is too caustic for the mouth). If the ingredients in a tablet are too harsh to be chewed, pulverize the tablet and eat it with applesauce, yogurt, pudding, or something similar.

The most absorbable supplements, and those which many practitioners prefer, are in liquid form. Many liquid supplements are *colloidal*, whose tiny particles don’t require much work from the digestive tract. *Ionic* nutrients, even smaller particles than colloidal, carry a beneficial charge that is often felt instantly. A recent development is *liposomal* liquids, nutrients encased in lecithin or other oils that escort the nutrient straight into the body’s cells. One company, VitalMinz, makes a complete formula of easily absorbed, ionic and liposomal vitamins and minerals (see Appendix A).

The body is designed to extract what it needs and eliminate what it doesn’t; but very ill or debilitated people usually can’t do this. Also, genetic defects may prevent the body from efficiently metabolizing foods or even food-based supplements. Even concentrated food powders may not provide enough nutrition, especially for people dealing with severe deficiencies. Under such circumstances, liquid supplements are clearly the best choice.

Guidelines for Effective, Safe Supplements

People who are ill are starved for nutrients. To correct the deficit, one can obtain more nutrition from carefully crafted supplements. When used correctly, nutritional supplements do what the name suggests: they *enhance*, *reinforce* or *supplement* the body's vitality, thereby making a huge difference in how we feel and function. Vegetarian supplements are fine, though sometimes animal products such as glandulars are needed. (See Sidebar, "Glandulars.")

Food-based supplements are dehydrated, concentrated powders of mostly fruits and vegetables, available as tablets, capsules and occasionally liquids. Often, the co-factors (enzymes, minerals and other substances) that accompany vitamins when they're in food are not included in synthetic vitamins. This is why it's wise to take single-nutrient supplements with food or food-based supplements.

Synthetic vitamins are processed in a laboratory. Nevertheless, they can be of high quality, especially if they're extracted from plants instead of toxic materials. If you take synthetic vitamins, make sure they're not manufactured from coal tar, other petroleum products, noxious chemicals, or GMOs. Avoid supplements from China, which routinely exports contaminated products. Supplements should not contain fillers, binders, excipients or additives, many of which are potentially allergenic. Sometimes, however, the benefits of the nutrients may outweigh the harm of their additives.

Opponents of nutritional supplementation like to cite research demonstrating the harm caused by vitamins. But what the public is not told—and what such studies often fail to disclose—is that synthetic vitamins are being used! That said, plant-based vitamins are not always the most

helpful, and synthetic supplements are not always harmful. The body may utilize food-based supplements better than synthetics, but not always. The question to ask isn't "Is it natural or synthetic?" but rather, "*Can this be absorbed and utilized by the body with optimal benefit?*" Because human beings can't always absorb, metabolize, convert or utilize the nutrients in foods, synthetic vitamins can be extremely helpful, as long as they're used properly and don't cause undue stress. In fact, a representative from food-based Standard Process once told me privately, "Sometimes synthetic vitamins are necessary—especially when people are so ill that their bodies need a massive push and nothing else will work. We don't live in a perfect world."

People sometimes fear that if they keep taking supplements, eventually the body won't be able to function without them. Annemarie Colbin writes that taking a lot of supplements may cause excessive hunger, because you'll crave the bulk that normally accompanies concentrated nutrients. But because those who are ill tend to suffer from severe nutrient depletion, high amounts are needed to correct the condition. Nevertheless, if you're ingesting high amounts of just a few nutrients, be careful that you aren't unbalancing the ratios of other nutrients in the body.

How do you know if your supplements are effective and safe? Ask the company the source of ingredients and how they are processed. Most people don't know that major (and some smaller) supplement companies hire the same manufacturing plants to supply their tablets and capsules. There's no substantial difference between brands, except perhaps for the fillers and binders that are used. To ensure quality, buy from companies that value full disclosure.

Glandulars

One type of supplement is comprised of the raw glands and organs of animals (mainly cattle) who ideally are raised without hormones or antibiotics. The animal material is usually processed via freeze-drying. Such supplements commonly include the thyroid, liver, adrenals, pancreas, kidneys, ovaries, testes, pituitary and thymus; but they can also be comprised of lymph, spleen, brain, gallbladder, kidneys, heart, and salivary glands.

Tests conducted in Germany by Dr. A. Kment, and published in 1958 and 1972, revealed something remarkable. By tagging a radioactive isotope onto organ or gland tissue and then injecting it into a recipient, Dr. Kment discovered that *the organ or gland tissue from the donor has an affinity for the same organ or gland in the recipient*. For example, donor thyroid tissue is absorbed by the thyroid of the recipient, donor liver is absorbed by the recipient's liver, and so on. Incredibly, the cellular attraction is *organ-specific* and *not species specific*. This remarkable affinity is the basis of modern injectable cell therapy.

Although Dr. Kment performed his tests with injectable glandular material, subsequent researchers have found that even when eaten, organ and glandular material survives the stomach acid and travels to the corresponding organ or gland in the recipient's body. This is undoubtedly why our ancestors felt that eating such foods bolstered their strength—and why modern-day folk with depleted or weak organs and glands can be helped with supplementation. Help your dog by feeding it small amounts of raw organs and glands from cows, sheep, goats, deer, elk, or similar animals. Most dogs love these meats and thrive on them. Humans who want to strengthen their liver, kidneys or heart might want to add these (cooked) foods to their own diets as well.

Absorbable Minerals From Dr. Hans Nieper

Many important biochemical reactions in the body cannot occur if there's a mineral deficiency. For example, zinc is needed for more than 200 enzyme reactions and magnesium is needed for more than 300. But getting a tablet from the digestive tract into the bloodstream is only the first step. A nutrient helps the body only if it can pass through a cell membrane to the inside of the cell where it's finally utilized. Sometimes a cell membrane isn't permeable—common in people with severe illness and degeneration—because it's structurally damaged or some of its metabolic pathways are blocked. This corresponds to weakened or incorrect electrical charges on the inside and outside of the cell. In such cases, a mineral will simply circulate through the bloodstream until it's filtered out by the kidneys, leaving the tissues starved.

One way to get nutrients into severely ill people is to intravenously saturate the bloodstream with nutrients at such high levels that some of the nutrients are forced into the cells solely from pressure. However, intravenous delivery is expensive and must be administered by a licensed medical professional. Also, saturating the bloodstream with excessive amounts of certain nutrients can create an imbalance of others. An easier, safer and less expensive way is to orally ingest minerals bound to other substances called *transporters*.

In the 1950s, German medical doctor Hans Nieper developed four different classes of mineral transporters—*aspartates*, *orotates*, *arginates*, and *2-AEP* (short for *2-aminoethanolphosphate*)—each of which has an affinity for different types of body tissue. This specific targeting allows the minerals to enter, nourish and repair the organs, glands and other tissues that need them. The formulas are designed for absorption even by people with poor digestion and impaired cell membranes. The transporters not only escort the minerals across cell membranes, but offer benefits in their own right, such as supporting energy production and protein synthesis.

Nieper's formulas compensate for the relatively low absorption rates of some forms of minerals (including lactates, citrates and gluconates), which can be unfavorably transformed by the stomach acid. Bound to their transporters as they enter the bloodstream from the small intestine, the intact Nieper minerals aren't released until they enter the cells. To illustrate: Medical doctor, neurologist and clinical nutritionist Steve Hiltiwanger points out that 600 mg of elemental magnesium, taken as magnesium oxide, has an absorption rate of 9%, resulting in only 54 mg of magnesium that can actually be utilized. Even liquid ionic (colloidal) magnesium may require extra steps to cross cell membranes, because it's repelled by the

cell's electrical charge. However, when taken with a transporter, *all* of the magnesium is utilized.

Here's a brief summary of the mineral transporter functions, along with (if applicable) the organs, glands and tissues for which the transporters have an affinity.

Aspartates. Deliver minerals to the outer cell membranes of muscle, bone, glands, heart, liver and breast. Depending on the minerals they're paired with, they:

- ◆ Recalcify bone
- ◆ Protect against cardiac ailments
- ◆ Inhibit tumor activity, protect against cancer, and support general immunity
- ◆ Increase insulin production
- ◆ Detoxify the liver (by helping to remove ammonia)
- ◆ Reduce tension in the lungs (thus alleviating asthma)

Orotates. Depending on the minerals they're paired with, they:

- ◆ Recalcify bone
- ◆ Are anti-inflammatory and help relieve pain
- ◆ Help with neurological disorders: depression, mood swings, migraines, and headaches
- ◆ Protect the heart, help prevent hardening of the arteries, and reduce serum cholesterol
- ◆ Protect the kidneys (when used with zinc aspartate)
- ◆ Inhibit the ability of viruses to replicate
- ◆ Maintain the balance of potassium in the body

Arginates. Deliver minerals to the plasma as well as to the outer cell membranes. Depending on the minerals they're paired with, they:

- ◆ Lower blood sugar levels
- ◆ Help alleviate inner ear hearing loss
- ◆ Transport fats into the mitochondria (the fuel-burning units of the cells that utilize fatty acids)
- ◆ Support immunity

2-AEP (2-aminoethylphosphate). Helps maintain the cell's normal electromagnetic field, thus allowing nutrients but not toxins to enter. Favorably affects membrane composition and permeability in:

- ◆ Myelin (the fatty sheath covering nerve cells)
- ◆ Bone
- ◆ Kidney glomeruli (tubules that clean the blood)
- ◆ Linings of the capillaries
- ◆ Pulmonary alveoli (small air spaces in the lungs where carbon dioxide leaves the blood and oxygen enters)
- ◆ Arteries in the retina of the eyes

Unfortunately, the company that sells Nieper's original formulas has also put fillers in many of the products. You may want to look for similar formulations elsewhere.

One food-based company is Standard Process, which owns acres of farmland on which it grows organic vegetables. After the vegetables are picked, they're dried at very low heat. The non-nutritive fiber is removed, and the remaining mass is concentrated and put into tablets and capsules. Many of the supplements are pleasant tasting enough to be chewed. The Standard Process vegetable-based products, many of which are made from organically farmed produce, are relatively clean. However, in recent years the glandular-based products have not been from organically raised animals due to the company's inability to meet a high consumer demand. (The company removed this information from their website several years ago.) Another good whole foods brand is Innate Response. A few more popular food-based supplement companies are HealthForce, Mega Food and Pure Synergy, although new manufacturers are constantly being created. An excellent company for herbal formulas is Medi-Herb (affiliated with Standard Process), and two others that bear the names of the herbalist-naturopaths who founded them: Dr. John Christopher and Dr. Richard Schulze. As people become more health conscious, there will undoubtedly be more companies making good products. However, as with synthetic supplements, there may be ingredients that your system doesn't need, as well as harmful fillers and binders. You must read the labels of even food-based supplements.

People who are in fairly good health, or are on a wellness maintenance program, may feel best when taking food-based multiple vitamins and minerals. Those who are seriously ill, or suffer from hard-to-manage stress, may want a food-grade multiple vitamin and mineral complex (to obtain all co-factors that whole foods provide), along with high amounts of whatever bioavailable synthetic nutrients they particularly need. People who have difficulty converting folate or other vitamins into what the cells ultimately use, will need to supplement. In these cases, synthetics work better than "natural." And because humans cannot manufacture ascorbic acid in their bodies, taking extra Vitamin C may be mandatory. One excellent form is *liposomal*, which easily gets into the cells. See Sidebar, "How To Make Liposomal Vitamin C."

One more thing. Cost is usually a factor when choosing a health regimen. People with high nutrient requirements might have to spend thirty times more money on food grade supplements to get the results they would have achieved with fewer synthetic nutrients. Those suffering from severe infections, longstanding degenerative conditions, or an unhealthy lifestyle (such as daily alcohol or smoking), require immediate intervention. Food-based supplements may simply work too slowly to cause the necessary changes in a rapid enough time period. Don't be afraid to combine synthetic and food-based.

How To Make Liposomal Vitamin C

People who are very ill require high amounts of Vitamin C (grams, not milligrams). But 12 grams taken orally can cause diarrhea, and intravenous drips are expensive and must be administered by licensed medical personnel. With *Liposomal Encapsulated Technology* (LET) Vitamin C, phospholipids (fats) and Vitamin C are blended into a solution under so much pressure that the lipids surround the vitamin. Taken orally, the solution bypasses the digestive tract and travels throughout the bloodstream, crossing the cell membranes directly into the cells.

Commercially manufactured LET Vitamin C is expensive. You can make it yourself and get promising results for a lot less money. This homemade solution is about 70% encapsulated.

Ingredients and Equipment

- ◆ **A 2-cup Ultrasonic Cleaner.** You can use a high-speed blender, but you'll get better results with an ultrasonic cleaner.
- ◆ **Lecithin (granulated).** If your lecithin is made from soy, make sure it's not genetically engineered. (Most people who are allergic to soy can tolerate its lecithin). If you don't want to use soy, you can now buy granulated lecithin from sunflower. Liquid sunflower lecithin clumps and is hard to dissolve.
- ◆ **Ascorbic Acid (Vitamin C).** Most ascorbic acid is made with genetically engineered corn from China (which is notorious for selling toxic and contaminated products). Use ascorbic acid powder made from beets or cassava. Manufacturers constantly change their formulas, so you'll have to investigate to find a suitable Vitamin C powder.
- ◆ **Distilled water.** Bought from the supermarket, it will be contaminated with plastic. It's better to buy your own distiller (for about one hundred dollars).

Directions

1. Completely dissolve 3 level tablespoons of lecithin in 1 cup of distilled water in a quart jar.
2. Dissolve 1 tablespoon of ascorbic acid powder (Vitamin C) in ½ cup of water in a separate jar.
3. Pour dissolved Vitamin C solution into the quart jar holding the dissolved lecithin, cover, and shake.
4. Pour entire mixture into the ultrasonic cleaner bowl and keep the unit running until the fluid is homogenized. It will have a milky appearance.

If your ultrasonic cleaner automatically stops, keep pushing the "on" button to continue. Repeat for about 12 minutes. You may keep the cover open and stir the fluid with a plastic or wooden spoon to facilitate mixing.

Yields: about 12 grams of LET Vitamin C. Refrigerate.

This process is now being used for many substances, including Coenzyme Q10, essential oils, and more.

Food and Nutrient Allergies

Some people say that they're "allergic" to a vital nutrient such as iodine, or to foods that contain these nutrients. It doesn't make sense that one would be "allergic" to a vital nutrient, so let's explore this.

Take "allergies" that cause headache, fatigue, skin rash, etc. that some people report—as with an iodine "allergy." These symptoms are *detox reactions* that occur when the iodine dislodges poisons from the iodine receptor sites and the toxins circulate through the bloodstream. Address this possibility first. A *food intolerance* (which many call an "allergy") is the body's inability to absorb or assimilate nutrients from a food, and is usually related to insufficient enzymes or another digestive malfunction. Then, consider a true *immune-mediated allergy* (there are several types), in which the immune cells overreact in response to the ingestion of a food or nutrient—sometimes even attacking the body's own tissues.

To react adversely to a vital and necessary nutrient might be called the body's "errors of judgment." A number of protocols have been designed to address these errors. One is NAET (Nambudripad's Allergy Elimination Technique), developed by Devi Nambudripad, MD, DC, LAc, PhD. In this paradigm, an "allergy" is a processing error by the body that's triggered by an "allergen" or irritant—any food, nutrient, chemical, or even emotion that the body cannot manage correctly. Various stressors cause the acupuncture meridians to become unbalanced with too much, not enough, or stuck *chi* (life energy). The unbalanced energy then causes malfunctions in glands, organs, the nervous system, and muscles. Once the blockages are cleared, the body-mind can utilize nutrients, repair and build tissue, and remove wastes—i.e., function.

Gary Craig's Emotional Freedom Technique™ is an easily learned, self-administered protocol. Tapping on acupuncture points on the body methodically, and in a certain sequence, breaks the unproductive electrical messages that keep the system looped in a negative reaction cycle. A related method uses an LED. The irritant is held close to or against the body while scanning the entire surface of each ear for 30 seconds with a low-level laser or LED. (The ears contain acupuncture points for the entire body.) This helps the body dump toxins. Some electromedical equipment works on a quantum or energetic level. One unit is the I.M.A.E.T.®, or Immune Modulation & Allergy Elimination Technology (see Appendix A).

If you aren't getting well with supplements, or you're a practitioner who has reached an impasse with a client, consider addressing the body's "errors of judgment."

Customizing a Nutritional Program

Some people are surprised or disturbed when told to take many supplements. "Why can't I simply take a multi-vitamin tablet in the morning and be done with it?" they exclaim—and then refuse to follow their protocol because "it's too hard to take so many pills." (Nevertheless, many of these same people don't question their allopathic doctor when told to take multiple pharmaceuticals.) Remember that when you're treating the underlying causes of a major malfunction (with nutrition) instead of merely masking symptoms (with allopathic medicine), many nutrients are required. A few good labs in the United States offer accurate, detailed nutritional profiles based on blood and urine samples. If you have a longstanding or complex condition, find a practitioner who can order and interpret such a test and also recommend supplements for you.

The number of brands and types of nutritional supplements can be daunting not only to laypersons, but also to health practitioners. Here are some facts to consider when choosing your supplement program:

- ◆ *Vitamins and Minerals Come In Many Forms.* For example, the same mineral can be bound to many different substances. Your unique metabolism may require magnesium citrate but not magnesium gluconate. Experiment to find what works.
- ◆ *Vitamins and Minerals Work Together.* Nutrients always work synergistically with other nutrients. Our needs can be many, especially if the condition took years to develop. Hence, a problem might not be alleviated with just one, two, or even three single nutrients.

Example #1: Calcium, that famous bone builder, cannot enter the cell without being escorted by its companion mineral, magnesium. To complete the process, you also need the minerals boron, phosphorus and potassium, along with Vitamins D3 and K. (One form of the vitamin, K2, is synthesized by friendly flora while K1 is from plants. The body uses them in different ways, so you'll need the right form, K2.)

Example #2: The liver undergoes four phases of detoxification. Nutrients required for just the first phase include Vitamins B2, B3, B6 and B12; folate; glutathione; flavonoids; and the minerals selenium, copper, zinc and manganese. In subsequent liver detox phases many of these same nutrients are required, with other nutrients as well. If there are insufficient levels of any nutrient during any phase, metabolic wastes and environmental toxins will linger in the body and eventually cause even more health problems, ranging from migraines and digestive disturbances to more serious conditions including cancer.

- ◆ *Source of the Vitamin or Mineral.* Let's say you have all the symptoms of a Vitamin C deficiency, but you don't feel better taking it—in fact, you feel worse. This doesn't mean that you don't need Vitamin C. Maybe you felt bad because your Vitamin C supplement was sourced from corn, and you either have a corn intolerance or else it was very likely genetically engineered. You need the right brand of Vitamin C that has been produced from beets or cassava.
- ◆ *Manufacturing Process of the Supplement.* Two companies manufacturing an identical vitamin or mineral use processes that may involve different enzymes, extraction ingredients, temperatures, etc. One of the manufacturing methods may agree with you while the other does not.
- ◆ *Excipients, Fillers and Binders.* You may be reacting negatively not to the nutrient itself, but to one or more of the additives in a tablet or even capsule.

It's an art to customize a protocol that gives the body exactly what it needs so it can repair itself. Just as with dietary requirements, there is no “one-size-fits-all” protocol for nutritional supplements. If you suffer from serious or chronic illness and cannot get well despite your best efforts, experimentation and research, consult a knowledgeable professional.

OXYGEN THERAPIES

Scientists have debated—based on geological testing of rock and polar ice core samples—how much oxygen was in Earth's atmosphere thousands or millions of years ago compared to modern times. While it's difficult to pinpoint exactly what percentage of oxygen used to be on Earth (and pointless to argue), we do know that in the last century, oxygen levels *have* decreased and it's harder to breathe. Millions worldwide suffer from asthma and emphysema. Even those without a diagnosis of respiratory disorders know, after taking one deep inhalation, that our atmosphere is becoming foul, especially in industrialized cities. We are literally starving for oxygen. On the Internet, photos have been circulated of pedestrians in China who routinely wear air filtration masks outside (independent of any other reason such as supposed protection from viruses). It's no surprise that Tokyo—with alarmingly high air pollution levels and more people per square mile than any other city in the world—has opened oxygen bars, where people congregate and inhale

oxygen. Oxygen bars now exist in the United States as well.

Our diminishing oxygen supply has cost us our health. Dr. Otto Warburg, who won the Nobel Prize for medicine twice (in 1931 and 1944), showed that a fundamental cause of all degenerative disease is oxygen starvation at the cellular level. Most viruses, fungi, bacteria and parasites are *anaerobic*, or suited to an oxygen-deprived environment. They are unable to survive in an *aerobic*, or oxygen-rich, environment. (Pathogens that can switch to surviving in either environment can't survive ozone.)

Oxygen therapy is not new. The three most common forms of oxygen—hydrogen peroxide, ozone, and hyperbaric (concentrated)—have been used therapeutically for over 100 years. Depending on which form you use, oxygen can help neutralize harmful microorganisms and toxins, strengthen the body's immune response, support normal body tissues, and optimize cellular metabolism. Oxygen therapies cannot be patented by drug companies, which is undoubtedly why the public doesn't hear more about their uses or effectiveness.

Hydrogen Peroxide

The chemical symbol for hydrogen peroxide is H_2O_2 , designating two atoms of hydrogen combined with two atoms of oxygen. Some of you may remember falling as a child and your mother applying hydrogen peroxide to the scrape on your knee. It stung as it bubbled, but the liquid did a great job keeping the wound clean because most pathogens can't survive in the presence of oxygen.

Hydrogen peroxide is applied to much more than skinned knees. Industry has long known of its valuable and almost unlimited applications. One source mentions “a special hydrogen peroxide [that] is manufactured for the semi-conductor industry. . . . The transistors and chips are cleaned in hydrogen peroxide just prior to assembly” because “dust of any kind would cause noise [in the finished electrical components] and create problems.” The cleaning is done in a special space called a “clean room” which, incredibly, is “up to 100 times cleaner than any operating room in a hospital!”¹⁷⁴

Hydrogen peroxide has food and agricultural uses. It acts as a dough conditioner, as a bleaching agent for food and food-related paper products, and is used in aseptic cardboard packaging for juices and other liquids. Seeds are soaked in H_2O_2 to make them sprout faster, and mature plants are sprayed with it to increase crop yield.

Hydrogen peroxide is so essential, it's produced by the body. Nathaniel Altman writes:

Mother's milk is an established and healthy food source of energy, proteins, vitamins and minerals. In addition to its value as a nutrient source, interest has arisen in the ability of milk to kill bacteria, viruses, fungi and in its anti-amoebic properties. . . . In addition to the immunoglobulins, . . . the antibacterial effect of milk proteins is generally mediated by the reaction of hydrogen peroxide.

—Al-Kerwi et al.,

"Mother's milk and hydrogen peroxide,"
Asia Pacific Journal of Clinical Nutrition, January 2005

Hydrogen peroxide is involved in all of life's vital processes and must be present for the immune system to function properly. The cells in the body that fight infection (known as granulocytes) produce hydrogen peroxide as a first line of defense against . . . parasites, viruses, bacteria, and yeast. It is also required for the metabolism of protein, carbohydrates, fats, vitamins, and minerals. As a hormonal regulator, hydrogen peroxide is necessary for the body's production of estrogen, progesterone, and thyroxine. It also helps regulate blood sugar and the production of energy in cells.¹⁷⁵

Along with its medical uses as a disinfectant, antiseptic and oxidizer, H_2O_2 is now routinely utilized for a wide variety of conditions—including circulatory disorders, infections and immune dysfunctions—in humans, pets and livestock. This is partly due to its ability to dilate blood vessels in the heart and brain, and stimulate the production of interferon (an immune regulator).

Physician William Campbell Douglass notes that since 1920, over six thousand articles have appeared in the scientific literature pertaining to the scientific applications of hydrogen peroxide. Douglass, who has personally treated many people and reports that he often (though not always) obtains good results, describes in *Hydrogen Peroxide, Medical Miracle* how H_2O_2 helps rid the body of harmful microbes. "The clinical benefit of oxygen saturation of tissue fluid from the oxygen produced by hydrogen peroxide may be of secondary importance" because even greater benefit is hydrogen peroxide's role as "a powerful oxidizer. . . . It will oxidize [burn up] toxic and nontoxic substances alike, which is completely separate from its role as an oxygen contributor."¹⁷⁶ Altman agrees. Although H_2O_2 delivers "small quantities" of oxygen throughout the body, he writes, its prime way of oxygenating the body is due to:

an extraordinary capacity to stimulate oxidative enzymes, which have the ability to change the

chemical component of other substances (like viruses and bacteria) without being changed themselves. . . . The presence of hydrogen peroxide enhances natural cellular oxidative processes, which increases the body's ability to use what oxygen is available.¹⁷⁷

One argument commonly made against hydrogen peroxide is its tendency to produce free radicals. The presumed free radical damage from oral H_2O_2 is challenged by Ed McCabe, who is so highly regarded as an expert on oxygen therapies that he has been nicknamed "Mr. Oxygen." In his book *Oxygen Therapies*, he writes that the body is so effective in attacking pathogens precisely because of the free radicals that the H_2O_2 produces.

Leukocytes (white cells in the blood) produce a natural hydrogen peroxide . . . which surrounds and destroys harmful microbes. The hydrogen peroxide breaks down into water and oxygen (O_1). This form of oxygen (O_1) is a free radical. Therefore, it is unstable. It attaches to the most unstable structure around it; a virus or harmful microbe fits the bill. It disrupts them electrically, and this kills the bacteria—or disrupts the virus—and the white cells digest the remains. Any leftover peroxide is neutralized by catalase, an enzyme. . . . The cycle of defense is complete. This is our immune system at work.¹⁷⁸

Keep in mind that the oxygen *singlet*, in the form of O_1 , does not harm healthy living tissue. If large amounts of leftover peroxide might be a problem, McCabe suggests taking the antioxidant superoxide dismutase (SOD) at least several hours away from the H_2O_2 to help neutralize it. Interestingly, the first physician to recommend taking H_2O_2 orally was Royal Rife's colleague, Dr. Edward Rosenow.

Despite hydrogen peroxide's potential, it may be the most controversial of all the oxygen therapies. Some holistic doctors administer H_2O_2 intravenously, but debate the safety of administering it orally. Douglass cites studies suggesting that H_2O_2 taken orally might cause erosion of the stomach lining and even cancer. And one doctor in private practice once told me that she treated a number of people suffering from ulcers or damaged kidneys due to long-term consumption of H_2O_2 . Nevertheless, it appears that ingested H_2O_2 may cause damage or discomfort only under certain conditions: if it's taken with food, if too much is consumed at one time, or if the person is deficient in certain enzymes that could help the body handle the large increase of hydrogen peroxide in the system.

Researchers disagree about what constitutes a safe oral dose. Both McCabe and Altman suggest rather generous

amounts of oral hydrogen peroxide for various purposes, but Douglass is more prudent. “I don’t think H_2O_2 is dangerous taken orally as long as the recommended dose is not exceeded (10 drops of 3% H_2O_2 , three times a day),” he writes.¹⁷⁹ Also—and this is important—the hydrogen peroxide must be taken when the stomach is empty. Otherwise, it will interfere with the digestion of food and cause nausea or even vomiting when it interacts with bacteria in the stomach. This is why veterinarians often suggest feeding a dilute solution of H_2O_2 to a pet to induce vomiting if the animal has swallowed a poison.

If you do decide to drink H_2O_2 , be aware that it comes in different dilutions and grades (purities). Only *food grade* H_2O_2 is pure enough to ingest. The 3% dilution H_2O_2 from the drug or grocery store is not food grade (edible). It also contains so-called stabilizers such as phenol, acetanilide, acetanilid, sodium stannate, and tetrasodium phosphate. Other strengths of H_2O_2 , used for bleaching hair or for medical research, also contain additives.

A common food grade hydrogen peroxide dilution is 9%, although I’ve also seen 35% and occasionally 50% for sale. Concentrated H_2O_2 must be diluted to at least 3% to be safe for the skin or internal consumption. Food grade H_2O_2 can be bought in some health food stores, or through the mail, for a reasonable price. It’s perishable, and must be refrigerated. For long-term storage, it can be frozen. The average consumer, who doesn’t have access to medically administered intravenous hydrogen peroxide therapy, may self-administer hydrogen peroxide at home to eliminate all kinds of infections from *Staph* to *Candida*. Some people object to hydrogen peroxide’s strange taste and unpleasant sensation when swallowed, so they mix it with aloe vera juice or a little bit of cinnamon.

Hydrogen peroxide helps eliminate infections in the ears and sinuses. Liberally spray a 3% solution of H_2O_2 , or put several drops of it from a dropper bottle, into one ear and then the other. Let it fizz in each ear for 10 minutes, keeping the head tilted (lying down on the side is best) so that the ear canal retains the H_2O_2 . Hydrogen peroxide can be added to a douche or bathwater. It also makes a wonderful mouthwash because it kills bacteria that cause gum infections. A 3% (or less) solution is held in the mouth for at least a minute and then expelled.

About one teaspoon is poured into a quart of pasteurized milk to prevent unwanted bacteria from growing. Grocers spray H_2O_2 on their fruits and vegetables to keep them fresh. And as a general disinfectant and cleaner, peroxide can be sprayed in the bathroom to get rid of mold. Hydrogen peroxide at 35% or (even better) 50% dilution can be used to eliminate fungus and other contaminants in swimming pools and hot tubs, in addition

to wells that supply drinking water. Ed McCabe’s books give the precise percentages of dilution.

Concentrated H_2O_2 must be diluted down to at least a 3% strength before using it anywhere on or in your body. *If highly concentrated H_2O_2 gets on your skin, it will burn it. If highly concentrated hydrogen peroxide gets into your eyes or ears, or if you drink it, you can seriously damage yourself.* You must dilute and use hydrogen peroxide with great care if you buy it in a concentrated form.

The caustic nature of concentrated hydrogen peroxide, however, does not indicate *inherent* toxicity. There’s a difference between toxicity due to *concentration* and toxicity based on *intrinsic harm*. Take genuine poisons, such as neurotoxins and petrochemicals. Even when diluted to 1 ppm (parts per million)—where one part chemical is dispersed in one million parts of water—the essential caustic or lethal effect of the chemical doesn’t change. On the other hand, concentrated food grade H_2O_2 loses its ability to cause harm when it’s diluted. In fact, dispersed in water, its qualities are totally altered. The human body itself manufactures very diluted H_2O_2 , which helps the system heal and function.

The principle of dilution affecting function also exists with hydrochloric acid. Highly concentrated hydrochloric acid is such a corrosive solvent that it is sometimes used by industry to eat through metal. Yet the acid is secreted by the stomach, and without it we cannot digest protein. Inherently, hydrochloric acid and hydrogen peroxide are not poisonous: we must simply be careful about the strength or dilution at which they are used. Hydrogen peroxide (as with hydrochloric acid) can be safe and beneficial when it’s handled properly and used in the correct proportions.

Considering all the medications, food additives, pesticides, and other toxic chemicals that our government allows on the market, I believe that the danger of H_2O_2 is overstated. People who take charge of their own health tend to do more research, and thus develop keener discernment, than those who give away their power to doctors and regulatory agencies. I see no reason why highly concentrated food grade hydrogen peroxide (more concentrated than 3%) should be avoided if you are careful when handling it. Don’t allow the bottle to tip. If buying in bulk, you’ll have to freeze it. Keep the container in a plastic bag in case of leakage. If you spill some on your hands (your skin will turn white), immediately rinse with water. If you spill it on surfaces or get it in your eyes, immediately flush with water. If you accidentally swallow too strong a solution, drink plenty of water, remain standing, and seek medical help.

If you don’t think you can correctly and safely measure hydrogen peroxide, consider aloe vera, a hardy warm-

weather plant that naturally contains H_2O_2 . Aloe is applied topically for wounds and is ingested for all kinds of infections and digestive tract disorders (including hemorrhoids). Also, try waterfall therapy; it's fun! The refreshing feeling you get when near a waterfall is not only due to its positive-effect negative ion content, but also to the naturally high concentration of H_2O_2 in the spray or mist. You can also buy products that contain therapeutic amounts of some form of oxygen.

When used correctly, H_2O_2 can help increase energy and improve immune function. Strong reactions to orally administered H_2O_2 may feel similar to a detox reaction that results from rifting. This could mean either that the hydrogen peroxide is working, or that the amounts are dangerously excessive. Read Ed McCabe's book before using it internally. You can find a doctor to administer it intravenously, but this is much more expensive (although more efficient) than an oral program. At the very least, you can use H_2O_2 externally and for disinfecting objects.

Ozone

The second form of oxygen therapy that a layperson can easily use is ozone. Oxygen is found in nature in a diatomic form (two atoms together), and thus has the chemical designation of O_2 . Ozone, also found in nature, is triatomic (three atoms together), and thus has the chemical designation of O_3 . O_3 is much more reactive than O_2 . After ozone is created, it immediately breaks into O_1 and O_2 . That extra lone atom of oxygen, O_1 , combines with whatever it touches in a process called *oxidation*, which commonly occurs with bacteria, viruses, fungi, toxins, and even fats.

Ozone is so effective and multifaceted that it's worth exploring in depth. First I'll discuss the history of ozone, including how it acquired an undeserved negative reputation. Then I'll explain how ozone deactivates dangerous microorganisms and toxins, and the best ways to use it.

History of Ozone

The word "ozone" comes from the Greek word *ozein*, which means "to smell." You may remember being outside and smelling ozone created by lightning after a thunderstorm. However, ozone more commonly is created by the sun's ultraviolet radiation, "produced constantly in the upper atmosphere as long as the sun is shining," writes ozone specialist Saul Pressman in *The Story of Ozone*.

Ozone is heavier than air, it . . . falls earthward. As it falls, it combines with any pollutant it contacts, cleaning the air—nature's wonderful self-cleaning system. If ozone contacts water vapor as it falls, it forms hydrogen peroxide, a component of rainwater, [which is] the reason why rainwater causes plants to grow better than irrigation with ground water.¹⁸⁰

Ozone was discovered in 1785 by a Dutch physicist, and named and synthesized in 1840 by a German chemist working at the University of Basel in Switzerland. In 1856, the gas was used to disinfect operating rooms, and in 1870 it was reported to purify blood in test tubes. Monaco was the first country to build a water treatment plant using ozone in 1860, followed by Holland, Germany and France. The Germans began injecting ozone

in 1898. Meanwhile in America, the Florida Medical Association published a work explaining how to use ozone therapeutically. Dr. John Harvey Kellogg first used ozone in sauna steam cabinets in 1881 at his naturopathic sanitarium in Battle Creek, Michigan, having written in his 1880 book *Diphtheria: Its Causes, Prevention, and Proper Treatment*: "Probably, no agent . . . for the purpose of purifying the air

of the sick-room . . . is so useful for this purpose as ozone, one of the most powerful disinfectants known."¹⁸¹ In 1896, Nikola Tesla patented his first ozone generator. He began selling ozonated olive oil to doctors for medical use in 1900.

Throughout the first half of the 20th century, a number of physicians and dentists published detailed accounts of successfully using ozone to treat a wide variety of diseases, including anemia, asthma, gout, hay fever, syphilis, many types of cancer, chemical poisoning, diabetes, influenza, pneumonia, gangrene, wounds, and even insomnia and strokes. A 1904 volume of chemist Charles Marchand's *The Medical Uses of Hydrozone* [ozonated water] and *Glycozone* [ozonated olive oil] shows that those substances had been approved by the US Surgeon General! In June 1909, Dr. William D. Neel of Chicago was awarded a patent for a device to treat many medical conditions. It combined ozone with aromatic (essential) oils for inhalation. During World War I (as was reported later in German medical journals), the Germans used ozone to treat many conditions including chlorine gas burns, gangrene, influenza, and trench foot. Today, ozone is successfully used not only for all of the previously mentioned ailments, but also for severe infections such as Lyme and Ebola. It's still highly effective for cancer. Even pathogens that are aerobic—or which can

Chemists do not usually stutter. It would be very awkward if they did, seeing that they have at times to get out such words as "methylethylamylophenylium."

change from being anaerobic to aerobic—can't survive in the presence of ozone, a kind of "supercharged" oxygen.

Despite the efforts of some prominent medical cartel members to eliminate ozone therapy as a viable medical treatment, doctors have continued working with ozone and reporting their successes. As of this writing, ozone is a medically recognized therapy in Brazil, Bulgaria, Chile, China, Colombia, Cuba, the Czech Republic, France, Germany, Hungary, Israel, Italy, Japan, Mexico, Poland, Romania, Russia, Singapore, Spain, Yugoslavia, some Canadian provinces, and fifteen US states. Ironically, ozone was part of mainstream medicine in the US from 1900 to 1933 before it was replaced by poisonous drugs.

Dispelling Negative Myths About Ozone

There has been considerable negative publicity concerning ozone near the Earth's surface. The United States EPA states that ozone works fine where it belongs—in the upper atmosphere, to shield us from the sun's UV rays. But, it claims, no amount of ground level ozone is good for you (although the agency "settles" for .08 parts per million as acceptable, as there will always be some ozone on the ground). We are told that ozone levels are most likely to be elevated from noon through early evening on hot, sunny days—a true enough statement, considering that the UV rays from the sun produce ozone, and the sun shines most strongly in the afternoon. But this information is used to persuade people to stay indoors!

The likeminded weather services in the United States and Canada issue a daily "ozone health advisory," which warns the public when these levels are "too" high. We constantly hear reports alleging the adverse effects of ozone, which include all kinds of respiratory irritation from shortness of breath and coughing to chest pain and asthma. It's hard to ignore allegations such as: "Automobile exhaust is the primary cause of ground level ozone and the most serious air pollution problem in the northeast."¹⁸² Or: "The poor air quality is due to elevated ground level ozone concentrations. Ozone is a major component of smog and is formed by the photochemical reaction of pollutants emitted by motor vehicles, industry and other sources in the presence of elevated temperatures and sunlight."¹⁸³ Even those sympathetic to ozone's medical uses sometimes erroneously claim that there's "good" and "bad" ozone. All these statements indicate a misunderstanding of what ozone is and how it works.

The best article I have read that explains the conflicting opinions about ozone is called "The Toxicity of Ozone: A Report and Bibliography." Written by Clark E. Thorp, acting Chairman of the Department of Chemistry and Chemical Engineering at the Armour Research Foundation

of the Illinois Institute of Technology, the article first appeared in the February 1950 edition of *Industrial Medicine and Surgery*. After conducting an extensive review of all the literature on ozone to date, Dr. Thorp realized that researchers differed so vehemently in its appraisal because *they were not analyzing the same gas*. The ozone in one study was created very differently from the "ozone" in another study. As the gas doesn't normally exist in high concentrations, it must be created with special equipment. Investigators who reported *no* (or intrinsically low) toxicity levels for ozone were creating it using *pure oxygen* from cylinders instead of mixed-gas air, and/or were also using *low current densities* in the machines that created the ozone. Investigators who reported intrinsically *high* toxicity levels for ozone were creating it using *mixed-gas air* instead of pure oxygen, and/or were using comparatively *high current densities* in the machines that created the ozone. The manner in which the gas was produced determined whether or not the final product was pure ozone, or a mixed gas that contained harmful nitrogen oxides—which appear when ozone is not made properly. *It's the nitrogen compounds that are toxic, not the ozone itself*.

Unfortunately, many of the researchers whose papers Thorp read did not know the difference between properly made pure ozone, and improperly made contaminated ozone—the latter of which could not accurately be called "ozone." "The majority of the reports claiming ozone to be a highly toxic gas are a direct result of the use of [certain] equipment in making toxicity studies," Thorp explained. And despite the fact that several different scientists "called attention to the harmful effects of nitrogen oxides in ozone as early as 1913, . . . no direct study of the influence of nitrogen oxides on the toxicity of ozone was published until 1941."¹⁸⁴ Thorp also pointed out that one researcher even misreported and later recanted. (Note that Thorpe referred to himself in the third person.)

After noting the work of Thorp previously mentioned, Hill, realizing that oxides of nitrogen had been present in his previous test, decided to rerun the test on an identical basis to determine if pure ozone had higher toxic limits. These later tests showed that pure ozone was definitely non-toxic in concentrations as high as 50 parts per million. As a final result of his work, Hill states: "*Pure ozone is not poisonous in any sense of the word as it breaks down in contact with the mucous membrane and oxygen only remains. For this reason, there are no cumulative effects and pure ozone may be breathed for long periods of time without harm, provided, of course, that immediate irritation of strong concentrations is avoided.*" [emphasis added]¹⁸⁵

Thorp's review of the literature showed that research subjects were quite comfortable with pure ozone of concentrations of up to 20 ppm (parts per million). However, when ozone was mixed with nitrogen compounds, levels of even just 5 ppm were intolerable. So, despite the well-researched scientific literature on ozone, most of the mainstream material on ozone is heavily flawed. What most people call "ozone" is the *contaminants* that *accompany* improperly created ozone. If cathode rays, radioactive emissions or high-voltage charge are present, and if the feed gas is mixed-gas air rather than oxygen, highly toxic nitrogen oxides and other compounds will be created along with the ozone. The pollutants surrounding ozone have nothing to do with the intrinsic qualities of ozone itself. Pure ozone is O_3 . Obviously, if ozone contains contaminants or is combined with other compounds, it's no longer O_3 , but something else. Ed McCabe comments: "Broadly saying 'ozone is toxic' is an uninformed opinion due to oversimplification. It's what you hear from the media, which usually only has time for 'one-liners.' . . . [If the ozone is] contaminated, the contaminants are the toxins, not the ozone used at proper levels!"¹⁸⁶

We can analogize misconceptions about ozone with leaving a bowl of beef stew out in the hot sun for many hours so it becomes contaminated with *Bacillus botulinum*, eating it, contracting food poisoning, and then deciding that stew is bad for you—instead of recognizing that you got sick because you ate spoiled food. Neither the

mainstream media nor government agencies seem willing to correct the misconceptions. Toxic contaminants in ozone simply highlight the need for clean sources of power, and for the manufacture of high quality ozone equipment that does not produce harmful chemicals. To save money, some manufacturers of ozone air cleaners use inferior components, which produce toxic compounds along with the ozone. Ethical manufacturers use better components, ensuring that pure ozone is produced.

Ozone therapy can be regarded as an electrotherapy, and must be dispensed correctly. The concentration of the gas must be high enough to kill aerobic pathogens without over-saturating the cells to the point where it damages them (see Sidebar, "Too Much of a Good Thing: The Immunosuppressive Effects of Ozone"). Likewise, if ozone is inhaled (discussed shortly), it must be done correctly.

How Ozone Works

How does ozone scavenge and decontaminate? In *Medical Applications of Ozone*, one scientist defines ozone as an "oxygen atom in the body on a rapid transit"¹⁸⁷—whether in the body, water, or air. The oxygen on rapid transit is *singlet oxygen*, the lone O_1 atom that breaks off from the O_3 cluster and leaves the O_2 (oxygen) behind. The power of ozone lies not in the O_2 , but in the O_1 atom. Dr. Pressman has stated that emphasizing the chemistry of ozone is misleading *because the therapy's effectiveness lies in its electrical nature. Ozone is the delivery system for the*

Too Much of a Good Thing: The Immunosuppressive Effects of Ozone

Ozone must be applied to the body in the right concentrations. The gas is a carrier of electricity in the form of O_1 atoms. The higher the concentration, the more electricity (electrons) are delivered. If too many electrons pass through a wire, you overload a circuit and blow a fuse. The body responds similarly.

Some information on ozone concentrations came from the research of Professor Bocci at the University of Siena, Italy. He took blood out of subjects, injected it with ozone, and returned the blood to the body. Then he measured the subjects' production of gamma interferon and interleukin 2. When plotted on a graph, the production of these immune substances showed a bell curve. The highest part of the curve lies at about 50 $\mu\text{g/ml}$, or micrograms of ozone per milliliter of blood. Below that concentration, it is less than optimal, disappearing at about 20 $\mu\text{g/ml}$. And above 50 $\mu\text{g/ml}$, it once again falls off, until about 70 $\mu\text{g/ml}$ the response is nil.

More information came from the research of Dr. Jon Greenberg of the Kief Clinic. He experimented with various concentrations of ozone on blood *in vitro*, to try to determine the maximum concentration that should be used. At 90 $\mu\text{g/ml}$, there was definite crimping and damage seen in the red blood cells. He recommended that medical therapy be limited to no more than 80 $\mu\text{g/ml}$.

Dr. F. Sweet and colleagues also did work on ozone concentrations, this time *in vitro* with cancer cells and normal tissue. They found that cancer cells were inhibited by ozone in a concentration-dependent manner. Normal cells were undamaged until a concentration of 70 $\mu\text{g/ml}$ was reached, beyond which their growth was suppressed.

It's clear that there is an upper limit on beneficial concentration for internal use, as well as a lower concentration threshold for ozone's effectiveness. All generators sold for medical use should reflect these established limits—with an output set at a single safe level, or controls to regulate the ozone flow. External use (limb bagging or funneling) can have higher limits, but care must be taken there as well.

—Saul Pressman, DCh, LTOH, 2007

O_1 electron. If the oxygen gas were doing the work, the O_2 that's routinely administered in hospitals would be sufficient to combat severe infections, and it's not. The electrical charge that ozone carries is so strong, it can literally blast a hole through the outer wall of a pathogen, killing even the ones that are aerobic (living on oxygen). In ozone therapy, O_1 is the safe and effective carrier of electricity into the body.

Among other functions, oxygen burns glucose. If there's not enough oxygen in the system, the glucose is incompletely burned, resulting in considerable metabolic debris. But ozone's high oxidative energy allows it to cleanly burn fuel as well as neutralize all sorts of toxins.

To the misinformed, ozone (singlet oxygen) might sound like a free radical. *Free radicals* are wild, unanchored atoms that try to stabilize themselves by stealing electrons from other atoms, thus causing severe tissue damage. But, unlike ozone, free radicals destroy healthy cells. Why doesn't ozone destroy healthy tissue along with pathogens and toxins? As mentioned earlier in the discussion on hydrogen peroxide, normal cells produce generous quantities of enzymes (including catalase and peroxidase) to protect cell membranes from oxidative damage. Damaged cells do not. Therefore, ozone (in the correct amounts) scavenges only unhealthy tissue and leaves healthy tissue intact. Even if healthy tissue is too saturated with toxins to produce sufficient protective enzymes, ozone is still beneficial. Oxidizing whatever toxins it touches, it will allow those cells to function again. Thus, properly administered ozone targets only substances that impair systemic function.

Ozone is also noted for normalizing immune function. It helps the body produce monocytes and lymphocytes (immune cells), as well as immunity biochemicals such as interleukin and interferon. If the immune response is overactive, ozone will calm it; but if the immune response is sluggish, ozone will raise its activity. Ozone also increases the activity of the mitochondria, small fuel-burning units of the cell. An abstract from a Russian study, "Influence of intravenous ozone treatment on the level of different specificity antibodies," states in part:

Medical ozone is the universal stimulator which participates in intracellular biochemical processes. Treatment with intravenous ozone was studied in 35 women [some of them pregnant], . . . three with anti-HLA antibodies, . . . three with anti-sperm antibodies, and seven with antiviral antibodies (*Herpes* 1, 2 and CMV). . . . Ozone is effective for . . . antibody levels in blood. *Medical ozone has direct antiviral activity which induces long term remission and in some cases total elimination of virus from blood. Generally, ozone is a modulator of*

*the immune system, stimulating . . . cell immunity. . . . Immune regulation . . . in pregnant women was increased. [emphasis added]*¹⁸⁸

Kurt Donsbach, DC, ND, PhD, summarizes that oxygen therapies:

- ◆ Increase tissue oxygenation, which brings about improvement in metabolic rate.
- ◆ Stimulate production of white blood cells, which are necessary to fight infection.
- ◆ Decrease blood carbon monoxide load, which frees hemoglobin to carry oxygen.
- ◆ Increase hemoglobin disassociation [the ability of hemoglobin in the red blood cells to let go of the oxygen they are carrying], thus increasing delivery of oxygen from blood to cells.
- ◆ Increase red blood cell flexibility, which allows them to squeeze through the smallest blood vessels more easily.
- ◆ [Break down] and degrade petrochemicals.
- ◆ [Inhibit] the growth of new tissues such as tumors.
- ◆ Increase the production of interferon and tumor necrosis factor, used to fight infections and cancer.
- ◆ Increase the efficiency of the antioxidant enzyme system, which scavenges excess free radicals.¹⁸⁹

Ozonated Drinking Water

Over 3,300 European cities treat their municipal drinking water with ozone. It's difficult to obtain figures for the US, but some cities that now ozonate their water supply include New York, Seattle, Dallas, Tampa, and Los Angeles. Ozone's half life of 12 minutes means that even if you're lucky enough to live in an area that ozonates its municipal water supply, you won't receive the additional benefits of ozone's pathogen and toxin neutralization inside your own body—or enjoy ozone's heightened cell and immune function—unless you add ozone to your water just before drinking it.

The best way to disperse ozone into drinking water is through a stone bubbler, commonly used to oxygenate aquariums. This can be bought at a pet store. Bubble a glass of water for about 10 minutes to saturate the ozone levels. A gallon of water requires about 45 minutes. If ozonated water is kept in the refrigerator at 40°F (7.2°C), the ozone will remain intact in the water for three to four days. Frozen in a plastic container, the water can be stored for several months. Filter the water first; otherwise, the ozone will be used up oxidizing contaminants in the drinking water, instead of doing its work inside your body.

If you're drinking ozonated water, do it on an empty stomach. Ozone's *oxidizing* properties will cancel out the *antioxidant* properties of various nutrients such as resveratrol, alpha lipoic acid, and Vitamins C and E. To avoid the conflict of competing agendas, drink ozonated water at least an hour *before* taking these supplements and wait 4–6 hours to drink it *after* taking them. Drink it at least one hour before a meal; and wait several hours after a meal to drink it so the food can digest first.

Ozone Insufflation

Insufflation refers to the introduction of ozone into the body through an orifice: the ears, rectum, or vagina.

Through the ears is a common (and simple) way to bring ozone into the body. As the gas travels easily, this method is very effective for clearing out the sinuses, the brain, and even sometimes the respiratory tract. Many people suffering from the brain fog of *Candida* and Lyme, or from hard-to-heal sinus infections, report at least partial, and often complete, relief. You can put the hose that emits ozone right to the ear. Some people take a stethoscope with the end drum removed, and attach the dangling hose of the stethoscope right to the output of the ozone unit.

For sinus infections, an alternative to ear insufflation is sinus irrigation using ozonated water. Use *only a few drops*, and let the water soak into the nasal tissues.

Administering ozone through the vagina is, of course, a special privilege of females. This is not only valuable for all sorts of vaginal infections, but it also helps detoxify the abundant lymph nodes in the groin that are accessible through the female genitalia. The only time this method is not advisable is during pregnancy.

Ozone gas by itself has also been administered via rectal insufflation. However, it's more common to ozonate water first, and then do a colonic or enema with the ozonated water. Ozone won't negatively affect the beneficial intestinal flora that thrive on oxygen.

Ozone Funneling and Limb Bagging

These phrases merely refer to concentrating ozone at specific areas where the skin has first been moistened. With funneling, a plastic funnel (available at kitchen supply stores) is attached to the silicone tube coming from the ozone generator, with the wide mouth of the funnel pressed against the part of the body that you want to affect. "This is especially effective with hepatitis, diverticulitis, pancreatitis and cancer," writes Saul Pressman. "It also involves the person in actively taking responsibility for initiating the healing process."¹⁹⁰ Dr. Pressman has seen very healthy babies whose mothers, when pregnant, funneled ozone over the belly. You can also funnel over the liver and colon for detoxification.

Bagging is typically used for limbs. A limb is placed inside a heavy, airtight plastic bag, along with the end of the tube leading from the generator. Then the open end of the bag is secured with a rubber band or string to make the bag airtight and keep the ozone inside. Bagging works nicely for arms and legs that have rashes, wounds, or cuts. This method has also been used to reverse gangrene.

Injectable Ozone

Ozone is sometimes directly injected into an artery or vein. This method requires a physician with considerable skill and experience. It's generally done for people who are seriously ill with degenerative and infectious illnesses. In Germany and other countries, doctors may remove someone's blood, infuse it with ozone, and inject the blood back into the body. Blood ozonation is especially popular for cancer, HIV/AIDS, herpes, and heart disease.

In the United States, physicians have lost their license and their practice for treating clients with ozone (as well as hydrogen peroxide). The Food and Drug Administration and the National Institutes of Health, reports Altman,

have refused to sponsor human trials for ozone and hydrogen peroxide and have made it extremely difficult for small independent companies . . . to undertake such research. Despite the fact that over 10 million people (including over a thousand AIDS patients) have received ozone therapy in Europe, and that reliable data on the use of ozone and hydrogen peroxide are supported by hundreds of scientific articles and clinical studies, the FDA maintains that bio-oxidative therapies like ozone have not been proven either safe or effective.¹⁹¹

Thus, seriously ill people must travel to Mexico or Europe for doctor-administered ozone treatments.

Breathing Ozone Through Oils

Critics of ozone like to point out the respiratory damage that occurs when ozone is inhaled. However, this is a half-truth, isolated out of context and used as a tactic to scare people away from a highly beneficial healing modality.

It's true that inhaling even uncontaminated ozone at too high a concentration through the nose or mouth over long periods can cause lesions or other damage in the delicate mucous membrane lining of the respiratory tract. However, as stated in *Medical Applications of Ozone*, although ozone is "toxic if inhaled, . . . it is only a local toxicity"—and the studies concluding that ozone had negative effects on animals "were done by only observing respiratory tract lesions after *long-term* inhalation of ozone." [emphasis added]¹⁹² Even this information from a

sympathetic source is misleading, though, because rats and mice—the most commonly used laboratory animals—are affected adversely because their lungs cannot clear fluid as rapidly as animals with more advanced lung protection mechanisms. Naturopath George Freibott clarifies this:

All I can say about ozone therapy is good things, as I have never seen it do harm to any patient yet. Even the Armour Report done in the 1950s states the following (this is the report on which most governments and many scientists base their *horror* stories about ozone and its *supposed* harmfulness): “Mice put in an *extremely* high flow of *concentrated* ozone developed pulmonary edema for two days, but by the third day the mice grew *strangely* resistant to the ozone and *no more* pulmonary edema was evident.”

The reason no more pulmonary edema was evident was because the *toxicity* or toxic elements *coating* the lungs of these mice was fully oxidized, neutralized and eliminated by day three! The substances being fully oxidized left nothing more for the ozone to oxidize, thus the pulmonary edema and the “sensitivity” disappeared. We have seen it work likewise in patients that have had different respiratory dysfunctions. . . .

I oftentimes work in atmospheres of ozone (in our laboratories) that exceeds the allowable EPA and FDA standards of allowable ppm (parts per million) by 52,000 times! I suffer *no* diminution in lung capacity (in fact it has increased over the years). We have given IA [intra-artery], IV [intravenous], IM [intra-muscular], and by inhalation, doses of ozone and oxygen therapies to patients for over 25 years personally, without any untoward side effects, ever.¹⁹³

Again, *the source of the ozone is critical*. If the gas is made improperly and contaminated with toxic chemicals, lesions on the lungs may form. But that’s not the fault of the ozone. Caution is advised, however; even a five-minute exposure can cause coughing due to irritation. If you cough, either you’re breathing harmful compounds (which is not very likely), or the ozone concentration is too high. Turn off the generator, open the window, or keep the generator on and leave the area.

Ironically, *the inhalation of raw ozone was never meant to be used as a medical therapy anyway*. Informed physicians and laypersons who use ozone for inhalation make sure to first pass it through suitable oils. The aromatic inhaler device invented by Dr. Neel was called “Process of Producing a Medicament [medication]” because the ozone,

Master Mineral Solution (MMS)

MMS is made by mixing together equal amounts of “unactivated” MMS (sodium chlorite) and food acid such as citric acid. This produces chlorine dioxide, (ClO₂), or “activated” MMS. Chlorine dioxide is often used for wide-scale water purification because it kills pathogens and destroys poisons. It became popularized as a germicide by aerospace engineer Jim Humble after a trip to South America, during which he discovered how safely and effectively ClO₂ helped people recover from malaria.

Don’t be scared of the “chlorine” in “chlorine dioxide.” Chlorine is part of the chemical compound salt (sodium chloride), yet only the uninformed would claim that salt is a poison. In his *MMS Health Recovery Guidebook*, Humble notes the chemical differences between (both unactivated and activated) MMS and chlorine. Chlorine dioxide is “totally different from common household bleach (sodium hypochlorite, which also has Cl in its chemical formula, NaClO) which is . . . known to be cancer causing. Chlorine dioxide (ClO₂) is not cancer causing and has an amazing ability to destroy (through oxidation) disease-causing microorganisms in such a manner that it is also destroyed at the same time, leaving behind only a few grains of plain table salt, discharged oxygen atoms, and dead microorganisms.”¹⁹⁴

Humble’s book gives detailed how-to instructions. He advises using small amounts, especially at first, to avoid die-off reactions. This fluid is cheap, effective, and safe when used properly. The FDA has tried to ban it—perhaps because MMS can reverse autism, as Kerri Rivera, the mother of a formerly autistic child, discovered (see kerririvera.com for details about her protocol). Dr. Stephanie Seneff believes that MMS can eradicate autism because it nonenzymatically breaks down glyphosate, which destroys the gut; and autistic children suffer from major gut issues.

Clearly, MMS is versatile. It’s an underused *oxidant*.

combined with high-terpene essential oils (such as juniper, pine and eucalyptus), atomized the oils into an unstable terpene gas that penetrated the lungs without causing an oxidative reaction. Thus, ten times more ozone was present in the lung tissue with no irritation at all.

Neel wrote in his patent application:

My experiments covering this long period have convinced me of its efficacy in curing consumption [tuberculosis], asthma and other diseases of the respiratory organs, as well as diseases of the blood. . . . this medicament, when properly administered, increases the

red blood corpuscles and hemoglobin and has a general beneficial action upon the system. . . . my invention may be said to consist in bringing an active oxidizing agent [ozone] . . . in contact with . . . terpene [oils], . . . the resultant product being administered to the patient in an inhalable form.¹⁹⁵

Today, variations of Neel's original device are used worldwide, with an expanded repertoire of oils that includes peppermint, spearmint and tea tree. However, ozone is more commonly bubbled through olive oil. When passed through olive oil, ozone is converted into a long chain *ozonide*, making it safe for lung tissue while still retaining the benefits of low dose ozone. Inhaling modified ozone has proven effective in treating all kinds of respiratory conditions, including asthma, bronchial infections and emphysema.

It's interesting that Neel used high-terpene pine oil with his ozone-breathing apparatus. For generations before him, oil of pine had been routinely used for healing. It was known as *turpentine*. Today, the compound we use for thinning paint is manufactured from petroleum, with a very different chemical composition. The history of this therapeutic ingredient has been largely lost (see Chapter 1).

Ozonated Olive Oil Salve

A unique way of utilizing ozone is as a salve. Nikola Tesla's original recipe called for ozone to be bubbled continuously through extra virgin olive oil for about three weeks. (The salve can be made in less time if the ozone generator is powerful enough.) This process changes the chemical composition of the olive oil several times. First the oil becomes naturally bleached. Eventually it gels into a very dense, paste-like, almost rock-solid consistency. German researchers have found that when the salve is kept refrigerated, it retains its effectiveness for over ten years. "When used during massage," Pressman reports, "the ozonide [the altered ozone in the olive oil salve] enters the tissue and oxidizes lactic acid and toxins, and this has proven to be an effective treatment for many skin problems,"¹⁹⁶ including burns, dry skin, fungal infections, insect bites, sunburn, sweat gland infections, and wounds.

People who are set up to breathe ozone through olive oil can produce a weaker, more runny version of this salve. It's not as good as the thickest, hardest concoction, but even this diluted form of salve has healing properties. As soon as ozone bubbles through olive oil for the purposes of breathing it, the oil becomes chemically altered. As you continue this therapy, eventually the oil becomes thicker and whitish. To make the very hard and even whiter salve, you must have an exceptionally sturdy ozone generator that can be left turned on for three weeks.

Oxygen Supplements

A few companies have created singlet oxygen formulas. Among the most common are magnesium oxide and calcium oxide powders. When mixed in water, they release ozone. Many people find the taste and sensation of these drinks similar to that of hydrogen peroxide—and equally unpalatable. More pleasant products contain *stabilized oxygen*. In most cases, though, ozone is taken in its gaseous form.

Ozone for Purifying Swimming Pools and Hot Tubs

Ozone is unparalleled for decontaminating any contained body of water. Unfortunately, it's relatively unknown and unavailable in the US. However, it's widely used in Europe. In fact, ozone is so common in Europe that when the Olympics was held in America, visiting overseas swimming teams—knowing how poisonous chlorine is—insisted that ozone, and not chlorine, be used to disinfect the swimming pools. (This was done, but after the Olympics ended, the ozone equipment was removed and chlorine was reinstated.) For most industrial uses, it's not critical that the ozone be strictly free of contaminants; but for medical use, the ozone must be pure.

Ozone Generators

To use ozone, you must invest in some type of ozone-producing equipment. Air purification units that emit ozone to help clean up contaminants indoors are useful, but they don't produce enough pure ozone for therapeutic purposes. Ozone equipment that makes medical grade ozone, and in high enough concentrations, can range in price from one to six thousand dollars.

There are several types of units that safely produce ozone. One low-power generator contains a specially designed ultraviolet lamp. It creates ozone from ordinary air by mimicking the activity of the sun. When the unit's narrow band of UV radiation reacts with oxygen, it creates ozone. Such devices are excellent for air purification or modest water purification. However, there's no way to increase the strength of a UV bulb, so the ozone concentrations remain far below what's necessary for most laboratory or clinical purposes.

Many ozone generators on the market utilize the *corona discharge* method, consisting of two metal rods that emit and receive current. Electrons jump from one rod to the other, generating an electrical field. Then the oxygen in the surrounding air splits apart and recombines to form ozone. (For instance, three molecules of O₂ will split and then re-form into two molecules of O₃.) Layers of quartz glass separate the metal rods to prevent the ozone from touching the metal and becoming contaminated. Corona

discharge generators can become quite hot. The heat created by the current tends to convert the ozone back into oxygen, so even more current is required to maintain a high enough ozone level. This is why corona discharge units are equipped with fans.

The better ozone generators on the market utilize the *cold plasma* method. Cold plasma was invented by Nikola Tesla in 1896 to eliminate the problem of excess heat typical of the corona discharge units. Instead of metal rods, he used glass rods filled with noble gas. The gas is a carrier for the voltage that jumps from one rod to another. (This electrostatic method is used for neon signs and some electromedical devices such as the Violet Ray.) When high voltage is sent through the rods, the oxygen between the rods becomes so energized by the field that (as with the corona discharge units) its molecules split apart and recombine to form ozone.

There must always be a source of oxygen in order for a generator to create ozone. Cold plasma technologies can be used for medical applications if they are supplied with pure oxygen. One source is an oxygen tank, which is filled with over 99% pure oxygen and must be refilled once the gas is depleted. Oxygen tanks used by welders contain the exact same high quality oxygen as the much more expensive medical oxygen tanks because welders require pure oxygen for their jobs. An alternative source of oxygen can be supplied from an oxygen concentrator. Using the ambient air in the room, an oxygen concentrator separates the oxygen from the other gases and then sends the concentrated oxygen to the ozone generator. Sending pure oxygen, rather than mixed-gas air, through these ozone generators guarantees that only oxygen and/or ozone are produced, instead of ozone and toxic nitrogen compounds, or ozone and other harmless but unwanted gases. Corona discharge units have high concentrations at low flow rates, and low concentrations at high flow rates.

Silicone tubing is used with all generators. It resists corrosion from ozone.

Ozone Saunas

Sauna therapy (discussed later in this chapter) is popular worldwide for both relaxation and toxin release. It's now becoming more common as well to use ozone in saunas. An ozone sauna is one of the best ways to receive ozone: the gas enters the entire bloodstream *transdermally*, or through the skin, as long as the skin is moist. (Sweating, with the optional addition of steam, will moisten the skin.) Once the pores are open from the damp skin, the ozone is readily transported into all of the tissues, including the lymph and fat. Ozone is especially helpful for cleaning the lymphatic vessels, which tend to get clogged on most

people. And, because fat cells hold the majority of the body's toxins, targeting them with ozone is very helpful. There's no need to be concerned about overdosing. After the bloodstream reaches its natural saturation point, the body simply does not accept any more ozone.

The only type of sauna that should be used with ozone is a cabinet, which allows the head to stick out of the top. An enclosed sauna room should never be used because (as mentioned earlier) ozone should not be inhaled except through olive and other oils.

Traditionally, steam saunas have been used with ozone. The steam opens the pores of the skin, and the heat from the steam also helps induce perspiration. But there's no reason why ozone cannot also be combined with a far infrared sauna cabinet, as long as you're able to sweat. If you have trouble perspiring, shower and leave some moisture on your skin before entering the cabinet. This acts as a "starter" for the body to perspire, but more importantly prepares the skin to accept the ozone.

All sauna cabinets used with ozone must be constructed of an ozone-resistant material. (See my book, *The Holistic Handbook of Sauna Therapy*, for a detailed list of materials.) Place the ozone generator near the cabinet and run the tube from the generator to the inside of the sauna through the opening at the top where the head sticks out. To avoid breathing in ozone, wrap a towel around the opening. A cheaper option than a sauna cabinet is a baggy nylon body suit, which covers the entire body except for the head and hands. The hose is inserted from the machine into any opening in the bag, which is sealed at the neck, wrists and below the feet (usually with velcro) to prevent ozone from leaking. Body suits should be made with ozone-resistant material. Portable, stiff, quilted cloth tents are also available. They fit over the body and allow the head and hands to stick out. Over time, the tents may degrade from the ozone.

Sweating by itself allows toxins to exit the skin without having to be processed (neutralized) first by the liver. Usually, this causes little discomfort. However, a sauna with ozone may cause intense itching because the ozone is rapidly oxidizing large amounts of toxic waste from the fat. The release of the proteinous waste through the skin may cause a very itchy rash. The itching can be alleviated somewhat or entirely by ingesting protease (protein-eating) enzymes—always on an empty stomach, so that the protease won't be used to digest food, but instead will be available to scavenge the debris in the bloodstream. Applying soothing creams or ozonated olive oil to the skin can also help with the itching.

Dr. Pressman suggests taking ozone saunas each day for half an hour, but admits that "the more frequent the

treatments, the more rapid the healing, and the more severe the healing reactions will be. It may become so uncomfortable that the person will need to reduce the frequency of treatments from once daily to once weekly.”¹⁹⁷ Other practitioners prefer a more moderate approach, such as 20 minutes three times a week.

If you have a heart condition, Pressman advises, for the first few sessions stay in the sauna for only 15 minutes, gradually increasing the time to 30 minutes to allow the body to adjust to the thermal stress. He does not advise ozone saunas for people with a history of strokes, because heat causes the blood vessels to dilate, which could potentially loosen another clot. However, he suggests administering ozone in other ways, such as funneling specific organs or areas of the body while in the sauna.

When combined with hyperthermia, ozone works wonderfully to reverse cancer because, Pressman writes:

Cancer tumor cells are tightly packed as they try to force their way in between other cells, and they are thus less able to shed heat. This accounts for the effect that heat stress has in killing cancer. Both heat stress and ozone kill cancer, so this treatment offers the best opportunity to eliminate cells which are fermenting sugar anaerobically, [and to] halt metastasis and restore healthy aerobic function. Ozone is able to seek out and destroy all the cancer cells with more certainty than the surgeon's crude scalpel. In addition, ozone will oxidize the toxins which caused the original problem, and thus prevent recurrence of the problem. This is in contrast to chemotherapy which is massively immune-suppressive, and radiation which causes cancer.¹⁹⁸

Although some of ozone's effects replicate or overlap with the effects of heat alone, the combination of ozone and body heating provides exponential benefits.

Versatile Within Certain Limits

People who don't enjoy drinking hydrogen peroxide, and who have the financial means, can purchase ozone equipment and give themselves ozone therapy for the rest of their lives in the privacy of their own home. Pure ozone—produced without contaminants and used correctly, at the appropriate concentration and flow rate—is safe, with healing applications for a wide range of conditions. However, while ozone works well for bacterial, viral and fungal infections (including cancer), it may not help much for nervous system conditions such as Multiple Sclerosis, stroke and cerebral palsy, or for injuries involving crushed tissue. Most neurological conditions respond better to hyperbaric oxygen therapy (next).

Hyperbaric Oxygen Therapy (HBOT)

Another therapy that uses oxygen is hyperbaric oxygen therapy, or HBOT. *Hyper* means “above” or “elevated,” and *baric* pertains to pressure. The benefits of breathing pressurized air were documented in the late 1660s. In 1834, the first hyperbaric tank was constructed by an iron shop for a French doctor, who reported excellent results treating many conditions. The first North American hyperbaric chamber was built in 1860. The use of HBOT for deep sea divers who surface too quickly from the ocean and suffer from “the bends” has been common since the late 1800s. However, hyperbaric oxygen for serious medical conditions has received professional validation and public recognition only in the last few decades.

For treatment, a person is immersed in an airtight chamber that contains pure oxygen, whose pressure is increased up to two times the normal atmospheric pressure—equivalent to what a scuba diver would experience at about 22 to 30 feet below the water surface. This increased oxygen pressure provides twenty times the normal concentration of oxygen to all the body's fluids and tissues. At the session's end, the oxygen level is gradually brought back to normal and the person leaves the chamber.

Hyperbaric oxygen is becoming more widely used as a therapy. Ordinarily, oxygen inhaled by the lungs is carried throughout the rest of the system by the red blood cells. Sometimes, though an area of the body with an inadequate number of capillaries, or someone with an especially high pathogen count, needs more oxygen than the red blood cells can deliver. “Because HBOT forces oxygen into the body under pressure,” write the authors of *Hyperbaric Oxygen Therapy*, “oxygen dissolves into all of the body's fluids, including the plasma, the lymph, [and] the cerebrospinal fluid surrounding the brain and spinal cord”—places that normally do not carry the gas. “These fluids can carry the extra oxygen even to areas where circulation is poor or blocked.”¹⁹⁹

Hyperbaric oxygen repairs tissue. The April 2006 edition of the *American Journal of Physiology—Heart and Circulatory Physiology* reported that HBOT increases the number of stem cells in the body by 800%.²⁰⁰ Stem cells, undifferentiated in the bone marrow, have the unique ability to travel throughout the body. When they land where they're needed, they become part of the cellular structure of that organ, gland or other tissue. This makes them invaluable for repair during injury and illness. HBOT also stimulates the growth of new capillaries in areas of injury.

Oxygen is vital to our health. It provides the fuel for all metabolic functions, kills many pathogens, strengthens the function of normal tissue, and stimulates growth of new healthy tissue. Thus, HBOT can help with:

- ◆ Injured soft tissue due to degenerative conditions such as diabetes and stroke.
- ◆ Necrotized tissue due to wounds, burns, and abscesses.
- ◆ Inflammation and swelling.
- ◆ Brain and nerve impairment, including from head injuries, brain damage, Multiple Sclerosis, cerebral palsy, and coma.
- ◆ Bone disorders, including fractures.
- ◆ Cardiovascular disorders, including loss of blood and anemia resulting from blood loss.
- ◆ Poisoning and damage from chemo, pharmaceuticals, carbon monoxide, insect bites, and even radiation.
- ◆ Many types of infections, including HIV, *Herpes*, and Lyme disease (however, ozone may be tried first).

Dr. Edgar End, clinical professor of environmental medicine at the Medical College of Wisconsin and Director of the Hyperbaric Unit at Milwaukee County General Hospital, once said: “I’ve seen partially paralyzed people half carried into the (HBOT) chamber, and they walk out after the first treatment. If we got to these people quickly, we could prevent a great deal of damage.”²⁰¹

Oxygen levels in the body just slightly higher than the therapeutic HBOT dose may cause temporary impairment of the lungs, ears, and central nervous system. People are advised to take time between treatments to recover from abnormal pressure to both the eardrum and the eyeballs. Increased oxygen levels mean metabolic changes in the eyes that may cause blurry vision: after 30 or 40 treatments, a few people have reported permanent nearsightedness (although HBOT is known for helping to restore vision after a stroke). *These unwanted “side” effects do not occur at lower pressures.* There are virtually no risks to HBOT if the right equipment is used in the correct manner.

The two classes of hyperbaric oxygen equipment are expensive, high-tech units used in hospitals, and chambers for the layperson. Machines designed for hospitals, which use more air pressure than home units, are potentially dangerous (which is why the therapy must be administered by qualified medical personnel). HBOT chambers for the home are incapable of administering too much oxygen because they’re designed for consumer safety.

For people who can self-treat—or receive help (if needed) to enter, leave and operate the chamber—a portable home cabinet is a wise purchase, especially if they need HBOT therapy on a regular basis. A one-time purchase (\$5,000) is less expensive than repeatedly seeing a doctor. Some companies rent HBOT units.

COLLOIDAL SILVER

History of Silver Therapy

For centuries, silver in various forms has been used for healing. The ancient Greeks and Romans used silver jars to keep stored liquids fresh. They wore silver frequently, perceiving that it maintained health. European royal families did not become as infected by the plague because they used silver utensils and ate off silver plates. And during the 1800s, American pioneers kept silver dollars in their milk jugs to prevent the milk from fermenting or spoiling. Silver coins were also dropped into water barrels to impede the growth of microorganisms and algae.

One of the first recorded medical uses of silver dates back to 1834, when a German obstetrician named F. Crede administered a 1% silver nitrate solution into the eyes of newborns to prevent blindness caused by eye infections. This practice continues today in hospitals worldwide. The Russians, as well as the National Aeronautics and Space Administration (NASA) in the US, revolutionized the water purification industry by using silver ions to purify the water in spacecraft. Today, water filters impregnated with silver are standard equipment in water filters.

The bulk of serious scientific study on silver appears to have begun in the early 1900s, with research correlating low plasma silver levels with infections. Versatile silver proved to be an effective healer when applied both internally and externally. It was put into the eyes, orally ingested, spread inside the nasal passages, applied to all kinds of wounds, and rubbed on the skin. It continued to be used therapeutically until the late 1930s.

In the 1940s, when the pharmaceutical industry began to create and promote synthetic antibiotics, silver as a healing agent became hard to find and its merits were no longer publicized. Silver’s fading popularity was also related to the forms in which it was being used. This was because it was combined with other substances to form compounds: silver proteins, silver nitrate, and other silver salts. Mild silver protein (MSP)—silver that’s bound to protein-rich gelatin to keep the large particles suspended in fluid—was common. It had such a low particle surface area that it was almost unusable by the body. Also, in some cases the proteins in MSP provided food for bacteria (thus encouraging their growth), and encapsulated the silver particles (preventing them from touching and thus killing the bacteria). Today, silver products over 100 ppm are likely to be MSP, and some MSP products are as high as 20,000 ppm. Silver compounds are less effective than pure *colloidal* or *ionic* silver, which are not combined with other substances. However, decades ago no reliable technology to make good quality silver fluid existed.

In the United States, colloidal silver is not approved for medical use. Companies that sell CS or the equipment to make it are forbidden by the FDA to tell the truth about colloidal silver's healing properties. Nevertheless, this has not stopped pharmaceutical companies from producing *other* silver products that *are* approved for medical purposes. These products include silver gels and creams (such as the widely used silver sulfadiazine) for cuts, burns and wounds; silver coated bandages, extensively and successfully used in hospital burn units; and various other silver compounds. The existence of these products makes it difficult for government agencies to continue to deny the health benefits of silver.

Disabling Pathogens

Silver is a broad-spectrum, safe, effective substitute for allopathic antibiotics. Research conducted since the 1970s has shown that silver:

- ◆ Deactivates the enzymes that microorganisms need for respiration. Because pathogens are suffocated rather than poisoned, resistant strains are unlikely to form (which happens with allopathic antibiotics).
- ◆ Oxidizes the pathogen in ways similar to those of hydrogen peroxide or ozone.
- ◆ Binds to the cell walls of bacteria, which prevents them from functioning properly and ultimately causes their death.
- ◆ Replaces sulfur and other substances in the cell wall that pathogens need.
- ◆ Repairs broken DNA of a virus—thus rendering it dysfunctional—because a virus, by definition, can only function inside a host if its DNA is incomplete.
- ◆ Weakens biofilms created by some pathogens such as *Staphylococcus aureus*. (See Chapter 5 for more information on biofilms.)

Here is just a small sample of the scientific proof that silver destroys bacteria, viruses, and many fungi—in fact, virtually any single-celled pathogen within minutes. In 1976, an article was published called “Antifungal Properties of Electrically Generated Metallic Ions.”²⁰² A 1978 *Science Digest* article reported that silver kills over 650 pathogenic microbes, and cited doctors who had developed silver compounds (and received the FDA's endorsement).²⁰³ A 2005 study showed that a silver ion solution destroyed *E. coli* by “readily” entering its interior.²⁰⁴ And in 2006, the *American Journal of Nursing* stated:

Silver is a broad-spectrum agent effective against a large number of Gram-positive and Gram-negative microorganisms, many aerobes [living in the presence of oxygen] and anaerobes [living in the absence of oxygen], and several antibiotic-resistant strains such as methicillin-resistant *Staphylococcus aureus* and vancomycin-resistant enterococci.²⁰⁵

The authors of a 2008 study, “Antibacterial Activity and Mechanism of Action of the Silver Ion in *Staphylococcus aureus* and *Escherichia coli*,” declared bluntly that there was a “significant reduction” in pathogens after a 90-minute treatment from “a silver ion solution that was electrically generated”—in other words, colloidal silver. “Transmission electron microscopy showed considerable changes in the bacterial cell membranes upon silver ion treatment.”²⁰⁶

Despite silver's versatility in killing bacteria and viruses, it cannot kill complex, multi-celled worms and similarly large parasites. However, it can kill the bacteria and viruses living *inside* the parasites. And although CS seems to help prevent viral infection, it may be less effective once an infection has become established. However, in such cases CS does prevent secondary infections from bacteria. It even helps improve the performance of pharmaceutical antibiotics. This makes it especially helpful for stubborn, drug-resistant infections.
